About the cover: Depiction of a model of the cholecystokinin B receptor, showing longitudinal views of the seven transmembrane helices (blue), the intracellular domains (yellow), i2 (red), and i3 (green), and the carboxyl-terminal tail (deep yellow). Mutational deletion of the carboxyl group from the Asp<sup>100</sup> residue in the TMII region (yellow) substantially weakened the ability of this receptor to couple to its G protein. From Jagerschmidt A., N. Guillaume, N. Goudreau, B. Maigret, and B.-P. Roques. Mutation of Asp<sup>100</sup> in the second transmembrane domain of the cholecystokinin B receptor increases antagonist binding and reduces signal transduction. Mol. Pharmacol. 48:783–789 (1995).
