ABSTRACT

Lipopolysaccharide (LPS) administration is a model of cholestasis. Organic anion transporting polypeptide 4 (Oatp4; Slc21a10) is almost exclusively expressed in liver. Therefore, it was hypothesized that LPS would down-regulate mouse Oatp4 and that this action is due to a decrease in nuclear binding activity of one or more liver-enriched transcription factors to mouse Oatp4 promoter. The present study indicates a time-dependent decrease in mouse Oatp4 mRNA levels by LPS. Moreover, LPS produced a rapid and profound decrease in nuclear binding activity to the mouse Oatp4 putative response elements for hepatocyte nuclear factor (HNF) 1, CAAT/enhancer binding protein (C/EBP), HNF3, and heterodimers of retinoid X receptor (RXR) and retinoic acid receptor (RAR). Maximal decrease in nuclear binding activity to these response elements preceded a significant reduction of Oatp4 mRNA levels. HNF1α bound to the Oatp4 HNF1 response element as a homodimer. Multiple copies of the Oatp4 HNF1α response element, inserted upstream of a minimal promoter, were sufficient to mediate reporter activity and responded to the coexpression of HNF1α in mouse hepatoma cells. Moreover, HNF1α dose dependently activated the Oatp4 promoter (~4.8 kilobases to +30 bp). Therefore, HNF1α is a potent trans-activator of the mouse Oatp4 promoter. In addition, Oatp4 mRNA levels were markedly decreased (95%) in HNF1α-null mice as compared with wild-type mice, suggesting that HNF1α levels are critical for the constitutive expression of the Oatp4 gene. Taken together, these findings suggest that the LPS-induced down-regulation of Oatp4 is likely due to reduction in the binding of HNF1α, C/EBP, HNF3, and RXR:RAR to the Oatp4 promoter.

Maintenance of bile flow and elimination of endo- and xenobiotics are facilitated by the coordinated regulation of hepatic transport proteins at the sinusoidal and canalicular membranes of hepatocytes. Some transport proteins are selectively or preferentially synthesized in liver. Expression of these transporters vary in response to a number of stimuli, such as the stage of liver development, or various pathophysiologic conditions, such as sepsis. Gene expression in liver is largely determined at the level of transcription initiation (Tavoloni and Berk, 1993).

Numerous genes are transcribed at much higher rates in hepatocytes than in other cell types, whereas “housekeeping” genes are transcribed at similar rates in many cell types (Powell et al., 1984). For example, the transcription rate of albumin is 1000-fold higher in liver than in other tissues (Powell et al., 1984; Liu et al., 1988). The high degree of liver-specific transcription is conferred by its regulatory sequence (Ott et al., 1984; Pinkert et al., 1987). The regulatory sequence of albumin contains response elements for several liver-enriched transcription factors involved in liver-specific expression, such as CAAT/enhancer binding protein (C/EBP), C/EBP-related protein, hepatocyte nuclear factor (HNF) 1, and HNF3 (Cereghini et al., 1987; Lichtsteiner et al., 1987; Herbst et al., 1989; Liu et al., 1991). Na+ /taurocholate-co-transporting polypeptide (Ntcp; Slc10a1) is another specifically liver-expressed gene. Ntcp is regulated by HNF1α, C/EBP, and heterodimers of retinoid X receptor (RXR) α and retinoic acid receptor (RAR) α (Trauner et al., 1998; Denson et al., 2000). It is widely accepted that activation domains of these liver-enriched transcription factors directly facilitate the assembly of ubiquitous transcription factors and RNA polymerase II onto the promoter (Ptashne and Gann, 1990). These transcription factors function in unique combinations to synergistically stimulate hepatocyte-specific transcription. Organic anion-transporting polypeptide 4 (Oatp4; Slc21a10) is expressed almost exclusively in liver of rats

ABBREVIATIONS: bDNA, branched DNA; C/EBP, CAAT/enhancer binding protein; HNF, hepatocyte nuclear factor; LPS, lipopolysaccharide; Oatp, organic anion transporting polypeptide; RAR, retinoic acid receptor; RXR, retinoid X receptor; Ntcp, Na+ /taurocholate-co-transporting polypeptide; ATCC, American Type Culture Collection; nt, nucleotide; kb, kilobase(s); bp, base pair(s); RLU, relative light unit(s); EMSA, electrophoretic mobility shift assay.
Liver-Enriched Transcription Factors in Regulation of Oatp4 695

Materials and Methods

Materials. DNA restriction enzymes, calf alkaline intestinal phosphatase, T4 polynucleotide kinase, and T4 DNA ligase were purchased from New England Biolabs (Beverly, MA). PfuUltra HF DNA polymerase was obtained from Stratagene (La Jolla, CA). Oligonucleotides were synthesized by Integrated DNA Technologies, Coralville, IA. Cell culture reagents, medium, and fetal bovine serum were obtained from the American Type Culture Collection (ATCC) (Manassas, VA). N,N'-Methylene-bis-acrylamide (2%), acrylamide (40%), lipopolysaccharide (serotype Escherichia coli 0111:B4), and protease inhibitors were purchased from Sigma-Aldrich, St. Louis, MO). Routine chemical and reagents were purchased from Fisher Scientific Co. (Pittsburgh, PA).

Animals and Treatments. Male C3H/OuJ mice (20–30 g) were purchased from The Jackson Laboratory (Bar Harbor, ME) and housed according to the American Animal Associations Laboratory Animal Care Guide. Mice were treated with a single i.p. injection of LPS (5 mg/kg) in a volume of 10 ml of saline/kg. Livers were dissected at 0, 1.5, 3, 6, 12, 16, 24, and 48 h after LPS administration (n = 5/time) and snap frozen in liquid nitrogen. Livers from wild-type and HNF1α-null mice were kindly provided by Dr. Frank Gonzalez (National Cancer Institute, Bethesda, MD). All tissues were stored at −80°C.

RNA Isolation. Total RNA was isolated from mouse liver using RNAzol B reagent (Tel-Test Inc., Friendswood, TX) according to the manufacturer’s protocol. The concentration of total RNA in each sample was determined spectrophotometrically at 260 nm. The integrity of each RNA sample was evaluated by formaldehyde-agarose gel electrophoresis before analysis.

Preparation of Nuclear Extracts. Mouse liver nuclear extracts were prepared by the method of Ganguly et al. (1997). Briefly, protease inhibitors antipain, pepstatin, and chymotrypsin inhibitor (2 μg/ml each), leupeptin and aprotinin (5 μg/ml each), trypsin inhibitor (10 μg/ml), and phenylmethylsulfonyl fluoride (0.1 mM) as well as phosphatase inhibitors NaF (10 mM) and Na3VO4 (1 mM) were constituents of the homogenization buffer. After extraction in the buffer [10 mM Hepes (pH 7.6), 400 mM KCl, 1 mM EDTA, 1 mM Na3VO4, 1% glycerol, 1 mM dithiothreitol, and 0.1 mM phenylmethylsulfonyl fluoride], the precipitate formed during dialysis was removed by centrifugation at 10,000g for 5 min, after which the extracts were aliquoted, snap frozen in liquid nitrogen, and stored at −80°C. Protein concentration was determined by the BCA protein assay obtained from Pierce Chemical (Rockford, IL).

Electrophoretic Mobility Shift Assays. The DNA sequence of the sense strand of each oligonucleotide is listed in Table 1. Oligonucleotides representing putative response elements of the mouse Oatp4 promoter for several trans-activators, namely HNF1 (nt –71 to –49), C/EBP (nt –317 to –298), and RXR:RAR (nt –146 to –126) based on a previous report (Ogura et al., 2000). Nuclear extracts (5–20 μg) were incubated with 2 μg of poly(dI-dC):poly(dI-dC) and 2 to 5 × 10^7 cpm of 32P-labeled oligonucleotides in the binding reaction mixtures. The binding reaction was performed on ice for 30 min, and then the entire sample was electrophoresed through a nondenaturing 4% polyacrylamide gel in Tris-glycine buffer at 12 V/cm at 4°C. Competition for binding specificity was performed using an appropriate amount of unlabeled specific oligonucleotides in the binding mixtures, along with the labeled oligonucleotides. For supershift experiments, nuclear extracts were preincubated with antibodies specific to HNF1α or HNF1β (Santa Cruz Biotechnology, Inc., Santa Cruz, CA) on ice for 2 h, and the binding reaction was performed as described above.

Plasmid Construct. A 15-kb KpnI fragment (−4.8 kb to +10.2 kb) containing 4.8 kb of the 5′ flanking region and 10.2 kb of the downstream sequence of the mouse Oatp4 gene was cloned by Dr. Kenichiro Ogura (Department of Drug Metabolism and Molecular Toxicology, Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan). Preparation of the 1.4 kb of the 5′ flanking region (nt −1424 to +30) entailed amplification of the fragment by polymerase chain reaction, using the downstream primer 5′-CTGAAACCCCCGGGTCCT-GAACAAGTGTTGC-3′ engineered with an SmaI site, and the upstream primer 5′-GGATCACAGGGCCCCCAAATCGAGG-3′ containing an ApaI site (nt −1423 to −1418). A reporter construct, p4.8kbOatp4-Luc (nt −4.8 to +30) was created by ligating the PCR-
amplified fragment (ApaI-Smal), the double digested fragment (KpnI-Apal), and the luciferase vector pGL3-Basic (Promega, Madison, WI). Three or five copies of the HNF1 response element (32 bp) were inserted into a luciferase vector pLuc-MCS containing a minimal promoter (Stratagene) to create p3xHNF1-Luc and p5xHNF1-Luc, respectively. The mouse HNF1α expression plasmid (pBJ5-HNF1α) was kindly provided by Dr. Gerald Crabtree (Stanford University School of Medicine). Host strain XL1-Blue competent bacterial cells (Stratagene) were used to propagate all plasmids. QIAGEN endotoxin-free Maxiprep kits (QIAGEN, Valencia, CA) were used to prepare plasmids for transient transfections. All plasmids were analyzed by restriction enzyme digestion, and DNA sequence was performed at the Biotechnology Support Facility of the University of Kansas Medical Center. The 4.8-kb 5′ flanking region was further confirmed by alignment with the mouse genomic database (www.ensembl.org).

Cell Culture and Transient Transfections. Mouse hepatoma HEPA1-6 cells were purchased from ATCC. Cells were maintained in Dulbecco's modified Eagle's medium (ATCC) supplemented with 10% fetal bovine serum (ATCC). Cells were seeded at 85 to 90% density in 24-well plates. To normalize for transfection efficiency, pRL-TK plasmid (Promega) coding Renilla luciferase under the control of a thymidine kinase promoter was cotransfected. For transient transfections, a DNA/lipid mix containing 3 μl of LipofectAMINE 2000 (Invitrogen, Carlsbad, CA) and 1 μg of plasmid DNA per well was used. For cotransfection of various amounts of pBJ5-HNF1α, the pB5 vector was used as carrier DNA. Cells were lysed with passive lysis buffer (Promega) 24 to 48 h after transfection. Luciferase activities were analyzed using a Dual Luciferase Reporter System (Promega) and were quantified in a Lumat LB 9507-2 luminometer (Berthold Technologies, Bad Wildbad, Germany).

Branched DNA (bDNA) Assays. Oatp4 mRNA levels in liver were determined by the quantitative branched DNA signal amplification assay (QuantiGene bDNA Signal Amplification Kit; Bayer Corp.-Diagnostics Div., Tarrytown, NY) (Hartley and Klaassen, 2000). Mouse Oatp4 gene sequence was accessed from GenBank (accession number AB031959). A multiple oligonucleotide probe set (capture, label, and blocker probes) specific to the mouse Oatp4 transcript (Table 2) was designed using ProbeDesigner software, version 1.0 (Bayer Corp.-Diagnostics Div.). Each probe developed in ProbeDesigner was submitted to the National Center for Biotechnology Information (Bethesda, MD) for nucleotide comparison by the probe sequence, and expressed sequence tags. The experiment was performed using the luciferase vector pLuc-MCS containing a minimal promoter (Stratagene) to create p3xHNF1-Luc and p5xHNF1-Luc, respectively. The mouse HNF1α expression plasmid (pBJ5-HNF1α) was kindly provided by Dr. Gerald Crabtree (Stanford University School of Medicine). Host strain XL1-Blue competent bacterial cells (Stratagene) were used to propagate all plasmids. QIAGEN endotoxin-free Maxiprep kits (QIAGEN, Valencia, CA) were used to prepare plasmids for transient transfections. All plasmids were analyzed by restriction enzyme digestion, and DNA sequence was performed at the Biotechnology Support Facility of the University of Kansas Medical Center. The 4.8-kb 5′ flanking region was further confirmed by alignment with the mouse genomic database (www.ensembl.org).

Target region refers to the sequence of the mRNA transcript as enumerated in the GenBank file. Function refers to the function of the oligonucleotide probe in the QuantiGene assay (i.e., CE, capture probe; LE, label probe; BL, blocker probe).

**Time Course of Nuclear Binding Activity to Putative Response Elements of the Mouse Oatp4 Promoter after LPS Administration.** To examine whether the LPS-induced decrease in mouse Oatp4 mRNA levels is associated with an
Effect of LPS on nuclear binding activity, the binding activity to mouse Oatp4 putative response elements for HNF1, C/EBP, HNF3, and RXR:RAR was performed using liver nuclear extracts prepared at various times after LPS administration. As shown in Fig. 3A, nuclear binding activity to these putative binding sites exhibited a time-dependent decrease and returned to control levels thereafter. The binding activity to putative response elements for HNF1 and C/EBP decreased maximally at 1.5 and 3 h after LPS administration, respectively, and returned to control levels by 12 h. Similarly, HNF3 and RXR:RAR response element exhibited a maximal decrease in nuclear binding activity to their putative response elements by 1.5 and 3 h after LPS treatment, respectively, and returned to control levels by 6 h after LPS administration. A consensus C/EBP oligonucleotide (Table 1) exhibited the same binding pattern as the Oatp4 C/EBP putative response element (Fig. 3A).

The time course of nuclear binding activities to the putative response elements of these transcription factors (Fig. 3) was compared with the time course of Oatp4 mRNA levels after LPS administration (Fig. 1). The maximal decrease in nuclear binding activities preceded the maximal decrease in mouse Oatp4 mRNA levels by about 9 to 10 h (Fig. 3). Moreover, the nuclear binding activities recovered before the mouse Oatp4 mRNA levels returned to control levels after LPS treatment. For example, as shown in Fig. 3B, LPS produced a rapid and profound decrease in nuclear binding to the Oatp4 HNF1 response element, which is prior to the LPS-induced decrease in Oatp4 mRNA levels (Fig. 1). The HNF1 binding activity returned to control levels around 12 h after LPS administration.

after LPS administration (Fig. 3B), and from that time the Oatp4 mRNA levels started to recover (Fig. 1).

The Oatp4 HNF1 Response Element Is Bound by HNF1α Rather than HNF1β. HNF1α and HNF1β are transcription factors of the variant homeodomain family (Baumhueter et al., 1990; Chouard et al., 1990). They have similar DNA binding specificity, although they are encoded by different genes. To determine the isof orm of HNF1 in the DNA-protein complex, supershift experiments were performed with antibodies specific to HNF1α or HNF1β. As shown in Fig. 4, a 100-fold molar excess of unlabeled specific oligonucleotide completely abolished the DNA-protein complex, suggesting that the DNA-protein complex was specific for the Oatp4 HNF1 response element. When antibodies specific to HNF1α were preincubated with liver nuclear extracts, they caused a further shift of the DNA-protein complex, whereas HNF1β antibodies did not (Fig. 4). Moreover, the entire band was supershifted by HNF1α antibodies.

The Oatp4 HNF1α Response Element Confers HNF1α Responsiveness. To investigate whether the Oatp4 HNF1α response element was sufficient to mediate reporter activity, mouse hepatoma HEPA1-6 cells were transfected with a construct containing three or five copies of the Oatp4 HNF1α response element (p3xHNF1-Luc or p5xHNF1-Luc) inserted upstream of the minimal promoter of the pLuc-MCS luciferase vector. The p3xHNF1-Luc and p5xHNF1-Luc constructs exhibited 11- and 14-fold higher reporter activities, respectively, compared with the vector pLuc-MCS containing the minimal promoter alone (Fig. 5). To further confirm that mouse HNF1α is able to activate reporter activity of p3xHNF1-Luc or p5xHNF1-Luc, mouse hepatoma HEPA1-6 cells were cotransfected with an HNF1α expression plasmid (pBj5-HNF1α) and either p3xHNF1-Luc or p5xHNF1-Luc. Coexpression of mouse HNF1α had no effect on reporter activity of the vector pLuc-MCS but up-regulated reporter activity of p3xHNF1-Luc or p5xHNF1-Luc by 30- and 40-fold, respectively. Moreover, five copies of the mouse Oatp4 HNF1α response element elicited a greater response to the coexpression of HNF1α than did three copies.

The Mouse Oatp4 Promoter Is trans-Activated by HNF1α. Previous studies indicate that an Oatp4 promoter (m4-137) was activated after cotransfection of HNF1α (Jung et al., 2001). The effect of HNF1α on a full-length Oatp4 promoter (−4.8 kb to +30 bp), containing numerous additional trans-acting factors, should further elucidate the importance of HNF1α. Mouse hepatoma HEPA1-6 cells were cotransfected with p4.8kbOatp4-Luc (nt −4.8 kb to +30 bp) and pBJ5-HNF1α. As depicted in Fig. 6, cotransfected pBJ5-HNF1α (150 and 350 ng) increased the reporter activity (−4.8 kb to +30 bp) by 5- and 6-fold, respectively. These data indicate that HNF1α activated Oatp4 promoter in a dose-dependent manner in mouse hepatoma cells through the 5′

flanking region (−4.8 kb to +30 bp), which contains numerous cis-acting sequences.

**Mice Lacking HNF1α Exhibit a Marked Decrease in Oatp4 mRNA Levels.** HNF1α-null mice were engineered by removing the first exon and the 5′ sequence of the first intron of the HNF1α gene (Lee et al., 1998). The dimerization domain of HNF1α is encoded by the first exon, which is indispensable for DNA binding of HNF1α. HNF1α-null mice exhibit impaired bile acid homeostasis, including bile acid synthesis and hepatic uptake of bile acids, as well as ileal and renal absorption of bile acids (Shih et al., 2001). As shown in Fig. 7, HNF1α-null mice exhibited a marked decrease (95%) in Oatp4 mRNA levels, compared with wild-type mice.

**Discussion**

Previous studies suggest that LPS-induced cholestasis is mediated by impairment of the hepatobiliary transporting systems involved in the formation of bile. To date, several genes encoding hepatobiliary transporters localized to sinusoidal or canalicular membranes of hepatocytes have been cloned. It has been shown that LPS-mediated repression of hepatobiliary transporters is principally the result of down-regulation of gene expression (Green et al., 1996; Moseley et al., 1996; Trauner et al., 1997, 1998; Vos et al., 1998). Consistent with these published studies on other transporters, the present data demonstrate that LPS treatment also produces a time-dependent decrease in mouse Oatp4 mRNA levels (Fig. 1). Oatp4 mRNA levels return to control values after a single injection of LPS, indicating that the effects of LPS on Oatp4 mRNA are reversible in this model. Among the rat Oatps, Oatp4 mRNA levels have been shown to be relatively high in liver (Li et al., 2002). Oatp4 mediates Na+-independent transport of bile acids and other organic anions across the sinusoidal membrane of hepatocytes (Kayko et al., 1999; Cattori et al., 2000). Finally, LPS reduces Na+-independent transport of organic anions in rodents (Bolder et al., 1997). Taken together, these studies suggest that Oatp4 might be a key player in the LPS-mediated reduction of Na+-independent hepatic uptake of bile acids and other organic anions.

Previous studies have shown that Oatp4 mRNA is expressed almost exclusively in liver of mice (Ogura et al., 2000) and rats (Li et al., 2002). However, numerous putative transcription factor binding sites are predicted by the analysis of the 5′ flanking region of mouse Oatp4 gene (Ogura et al., 2000). In the present study, mouse liver nuclear extracts exhibit binding activities to the putative response elements of four positive trans-acting factors (HNF1, C/EBP, HNF3, and RXR:RAR) (Fig. 2). Moreover, LPS decreases the nuclear binding activities to the HNF1α response element, and pu-
tative C/EBP, HNF3, and RXR:RAR response elements. The maximal decreases in nuclear binding activities to these re-
sponse elements occur prior to the maximal reduction of Oatp4 mRNA levels and return to control levels before Oatp4 mRNA levels start to recover (Fig. 3). These data suggest that the LPS-induced down-regulation of mouse Oatp4 mRNA might result from the reduction of trans-activation of Oatp4 promoter by HNF1α, C/EBP, HNF3, and RXR:RAR. It is widely accepted that liver-specific expression of genes is mediated by the concerted action of several liver-enriched transcription factors in a unique combination (Tronche et al., 1989). The present data suggest that HNF1α, C/EBP, HNF3, and RXR:RAR might be involved in the constitutive expression of the mouse Oatp4 gene, as well as the LPS-induced decrease in Oatp4 mRNA levels.

Liver-enriched transcription factors regulate liver-specific expression of numerous genes (e.g., albumin, transthyretin, Ntcp) (Maire et al., 1989; Costa and Grayson, 1991; Tronche et al., 1994; Trauner et al., 1998; Denson et al., 2000). Recent studies indicate that HNF1α is a key regulator of the hepatic uptake transporters (Jung et al., 2001; Shih et al., 2001; Jung and Kullak-Ublick, 2003). HNF1α and HNF1β exhibit equal binding specificity with HNF1 response elements. Moreover, the HNF1 response element can be bound by HNF1α homodimers, HNF1α-HNF1β heterodimers, and HNF1β homodimers (De Simone et al., 1991; Rey-Campos et al., 1991). Therefore, it was of interest to determine whether HNF1α and/or HNF1β bind to the HNF1 response element of the mouse Oatp4 promoter. The complex of DNA with HNF1β homodimers migrates faster than HNF1α homodimers, whereas the mobility of heterodimers is intermediate. The EMSA described in the present study indicates that there was predominantly a single band, and antibodies specific to HNF1α caused a supershift of the entire band, whereas antibodies specific to HNF1β did not. This suggests that the protein component of the DNA-protein complex is exclusively HNF1α (Fig. 4). Therefore, the present studies demonstrate that HNF1α binds to the Oatp4 HNF1α response element as a homodimer, and LPS decreases HNF1α binding to the mouse Oatp4 promoter.

The present study indicates that three or five copies of the Oatp4 HNF1α response element upstream of a minimal pro-
moter are sufficient to elevate basal reporter activity over that of the minimal promoter alone, probably due to the basal levels of HNF1α in mouse hepatoma cells (Fig. 5). Coexpression of mouse HNF1α increased the reporter activity of p3xHNF1-Luc from 11- to 30-fold and p5xHNF1-Luc from 14- to 40-fold. Moreover, five copies of the Oatp4 HNF1α re-
sponse element (p5xHNF1-Luc) conferred more responsiveness to mouse HNF1α than did three copies (p3xHNF1-Luc). Therefore, reporter activity linked to the multiple copies of Oatp4 HNF1α response element was dependent on the amount of mouse HNF1α, as well as the copy number of Oatp4 HNF1α response elements. In addition to the effect of HNF1α on the heterologous promoters containing the proximal HNF1α binding site and a TATA box, HNF1α activated the mouse Oatp4 promoter (−4.8 kb to + 30 bp) in a dose-
dependent manner (Fig. 6). Taken together, these data clearly demonstrate that HNF1α is a potent trans-acting factor of the mouse Oatp4 promoter.

The importance of HNF1α in the expression of the mouse Oatp4 gene was further confirmed in HNF1α-null mice. The present studies indicate that Oatp4 mRNA levels were decreased by approximately 95% in HNF1α-null mice, as compared with wild-type mice (Fig. 7). This finding clearly demon-
strates the importance of HNF1α for expression of mouse Oatp4 gene in vivo.

HNF1α mRNA is present in liver, kidney, intestine, pancreas, and stomach of adult mice (Baumhueter et al., 1990; Blumenfeld et al., 1991; Pontoglio et al., 1996). Therefore, the restricted expression of the Oatp4 gene to liver is probably not a function solely of HNF1α. In fact, it is accepted that liver-specific expression requires the concerted action of a unique combination of liver-enriched transcription factors, together with ubiquitous transcription factors (Tronche and Yaniv, 1992). The present studies suggest that C/EBP, HNF3, and RXR:RAR might be required for the constitutive expression of the mouse Oatp4 gene in addition to HNF1α. Further investigation would be needed to determine the role of these additional transcription factors in constitutive Oatp4 expression in liver.

In summary, the present data indicate that LPS decreases mouse Oatp4 mRNA levels in a time-dependent manner. The LPS-induced decrease in Oatp4 mRNA levels in liver occurs subsequent to the reduction of nuclear binding activity to the response elements of HNF1α, C/EBP, HNF3, and RXR:RAR, suggesting that these transcription factors might be involved in the LPS-induced down-regulation of Oatp4 mRNA. This observation supports the concept that liver-specific gene expression requires the concerted action of a unique combina-
tion of liver-enriched and ubiquitous transcription factors. Additionally, the present studies clearly demonstrate that HNF1α is a potent trans-activator of the mouse Oatp4 pro-
moter and activates the Oatp4 promoter as a homodimer. HNF1α levels are critical for the constitutive expression of the mouse Oatp4 gene. Together with a rapid and profound decrease in HNF1α binding to the mouse Oatp4 HNF1α response element after LPS treatment, these data suggest that HNF1α plays an important role in the LPS-induced down-regulation of mouse Oatp4.

Acknowledgments

We thank Dr. Michael Wolfe for discussions, Drs. Matt Dieter, Saul Karpen, and Kenichiro Ogura for technical support; Dr. Gerald Crabtree for the mouse HNF1α expression plasmid; and Dr. Frank Gonzalez for livers of HNF1α-null and wild-type mice.
