ABSTRACT

Vanilloid receptor 1 (TRPV1) is activated by chemical ligands (e.g., capsaicin and protons) and heat. In this study, we show that (2E)-3-[2-(piperidin-1-yl)-6-(trifluoromethyl)pyridin-3-yl]-N-quinolin-7-ylacrylamide (AMG6880), 5-chloro-6-[(3R)-3-methyl-4-[6-(trifluoromethyl)pyridin-4-yl]-4-(3,4,5-trifluorophenyl)-1H-benzimidazol-2-yl)piperazine-1-yl)pipridin-3-yl)methanol (AMG7472), and N-[4-(tertiarybutylphenyl)-4-(3-chloropyridin-2-yl)tetrahydro-2H-carboxamidine (BCTC) are potent antagonists of rat TRPV1 activation by either capsaicin or protons (pH 5) (defined here as group A antagonists), whereas (2E)-3-[(6-tert-butyl-2-methylpyridin-3-yl)-N-(1H-indol-6-yl)acrylamide (AMG0610), capsazepine, and (2E)-3-(4-chlorophenyl)-N-[3-methoxyacrylamide (SB-366791) are antagonists of capsaicin, but not proton, activation (defined here as group B antagonists). By using capsaicin-sensitive and insensitive rabbit TRPV1 channels, we show that antagonists require the same critical molecular determinants located in the transmembrane domain 3/4 region to block both capsaicin and proton activation, suggesting the presence of a single binding pocket. To determine whether the differential pharmacology is a result of proton activation-induced conformational changes in the capsaicin-binding pocket that alter group B antagonist affinities, we have developed a functional antagonist competition assay. We hypothesized that if group B antagonists bind at the same or an overlapping binding pocket of TRPV1 as group A antagonists, and proton activation does not alter the binding pocket, then group B antagonists should compete with and prevent group A antagonism of TRPV1 activation by protons. Indeed, we found that each of the group B antagonists competed with and prevented BCTC, AMG6880 or AMG7472 antagonism of rat TRPV1 activation by protons with pA2 values similar to those for blocking capsaicin, indicating that proton activation does not alter the conformation of the TRPV1 capsaicin-binding pocket. In conclusion, group A antagonists seem to lock the channel conformation in the closed state, blocking both capsaicin and proton activation.

Vanilloid receptor 1 (also known as VR1 and TRPV1) (Caterina et al., 1997; Montell et al., 2002) has been cloned and shown to be a nonselective cation channel with high permeability to calcium. TRPV1 can be activated by chemical ligands [capsaicin, resiniferatoxin, anandamide, 12-hydroperoxy-5,8,10,14-eicosatetraenoic acid, N-arachidonoyl dopamine, N-oleoyldopamine, and protons (pH ≤ 5.7)], and by physical stimuli, such as heat (>42°C) acting as an integrator of multiple noxious stimuli (Tominaga et al., 1998; for review, see Holzer, 2004; Szolcsányi, 2004). TRPV1 is abundantly expressed in peripheral sensory neurons and is thought to contribute to increased nociceptor function in pain states (Szallasi and Blumberg, 1999; Julius and Basbaum, 2001; Ji et al., 2002; Holzer, 2004). TRPV1 expression is increased after inflammatory injury in rodents, and the increased expression is reduced by treatment with capsaicin, resiniferatoxin, N-arachidonoyl dopamine, N-oleoyldopamine, and protons (pH ≤ 5.7). The differential agonism and antagonism of TRPV1 by capsaicin and protons suggests the presence of at least two distinct binding pockets. One binding pocket is required for capsaicin activation, and the other is required for proton activation. The two binding pockets are not the same, but they both require the same critical molecular determinants that are located in the transmembrane domain 3/4 region to block capsaicin and proton activation.

ABBREVIATIONS: TRPV1, transient receptor potential vanilloid type 1; BCTC, N-(4-tertiarybutylphenyl)-4-(3-chloropyridin-2-yl)tetrahydro-2H-carboxamidine; AMG9810, (E)-3-[4-(tert-butylphenyl)-4-(3,4-dihydrobenzo[b][1,4]dioxin-6-yl)acrylamide; AMG6880, (2E)-3-[2-piperidin-1-yl-6-(trifluoromethyl)pyridin-3-yl]-N-quinolin-7-ylacrylamide; JNJ-17203212, 4-(3-trifluoromethylpyridin-2-yl)piperazine-1-carboxylic acid (5-trifluoropyridinylacrylamide; AMG7472; TM3/4, transmembrane domains 3 and 4; DD161515, N-[3-[(3-phenoxyphenyl)methyl][(1H)-1,2,3,4-tetrahydro-1-naphthalenyl]propyl]glycyl-[N-[2,4-dichlorophenethyl]glycyl]-N-[2,4-dichlorophenethyl]glycinamide; AMG0610, (2E)-3-[(3-methoxyphenyl)acrylamide; AMG7472; SB-366791, (2E)-3-(4-chlorophenyl)-N-[3-methoxyacrylamide; JNJ-17203212, 4-(3-trifluoromethylpyridin-2-yl)piperazine-1-carboxylic acid (5-trifluoropyridinylacrylamide; AMG7472; TM3/4, transmembrane domains 3 and 4; DD161515, N-[3-[(3-phenoxyphenyl)methyl][(1H)-1,2,3,4-tetrahydro-1-naphthalenyl]propyl]glycyl-[N-[2,4-dichlorophenethyl]glycyl]-N-[2,4-dichlorophenethyl]glycinamide.
creased level of TRPV1 protein combined with the confluence of stimuli present in inflammatory injury states has been proposed to result in a reduced threshold of activation of nociceptors that express TRPV1 (i.e., hyperalgesia) (Ji et al., 2002). In agreement with this finding, TRPV1 knockout mice display reduced thermal hypersensitivity after inflammatory tissue injury (Caterina et al., 2000; Davis et al., 2000).

Several competitive antagonists of TRPV1 have recently been reported that prevent activation by different stimuli (for review, see Szallasi and Appenedi, 2004), such as BCTC [Valenzano et al., 2003, SB-366791 (Gunthorpe et al., 2004), AMG9810 (Gavva et al., 2005), AMG6880 (compound 49b in Doherty et al., 2005), JNJ-17203212 (Ghilardi et al., 2005), and A-425619 (Honore et al., 2005). Among the reported TRPV1 antagonists, AMG9810, A-425619, and BCTC inhibit hyperalgesia in models of inflammatory pain (Pomonis et al., 2003; Gavva et al., 2005; Honore et al., 2005), A-425619 reverses skin incision-induced thermal hyperalgesia (Honore et al., 2005), and JNJ-17203212 attenuates bone cancer pain (Ghilardi et al., 2005), supporting a role for TRPV1 in clinical pain states.

Among the reported TRPV1 antagonists, some compounds (defined here as group A antagonists) block both capsaicin and proton activation (AMG6880, AMG9810, and BCTC), whereas others block only capsaicin, but not proton activation (defined here as group B antagonists), in a species-dependent manner. For example, capsazepine blocks the proton activation of human and guinea pig, but not rat TRPV1 (McIntyre et al., 2001; Savidge et al., 2002). We have shown that SB-366791 blocks capsaicin, but not proton (pH 5) activation of rat TRPV1 (Gavva et al., 2005). These findings raise the question of whether the differential pharmacology of group A versus group B antagonists is a result of proton activation-induced conformational changes in the capsaicin-binding pocket of rat TRPV1 that alter antagonist affinities or if it is because they act through different binding sites on TRPV1 to block capsaicin and proton activation.

It is noteworthy that the ability of antagonists to block all modes of activation of TRPV1 seems to correlate with their in vivo efficacy in animal models of pain (Pomonis et al., 2003; Walker et al., 2003; Gavva et al., 2005; Honore et al., 2005). For example, capsazepine produced significant antihyperalgesic effects in a model of inflammatory and nerve-injury related pain in guinea pigs, but not in rats, correlating with its ability to block all modes of activation of guinea pig TRPV1 (McIntyre et al., 2001; Savidge et al., 2002; Walker et al., 2003). Likewise, AMG9810, A-425619, and BCTC, all of which block capsaicin, proton, and heat activation of rat TRPV1, were also effective as anti-hyperalgesics in rat models of inflammatory pain (Pomonis et al., 2003; Gavva et al., 2005; Honore et al., 2005). Hence, we are interested in understanding the differential pharmacology of antagonists and their mechanisms of action for blocking capsaicin and proton activation.

The aim of our study was to investigate whether the differential pharmacology of group A and B antagonists is caused by proton activation-induced conformational changes in the capsaicin-binding pocket of TRPV1 that alter antagonist affinities. This question would normally be addressed with radioligand binding experiments. However, tritiated resiniferatoxin is the only reported ligand that can be used in a competition-binding assay for TRPV1, and the assay is not optimal at pH 5 (Szallasi and Blumberg, 1993). Furthermore, the critical molecular determinants for resiniferatoxin affinity in binding assays and resiniferatoxin/capsaicin agonism (efficacy) in functional assays are also known to differ in TRPV1 (Acs et al., 1996; Gavva et al., 2004). In this study, by using a functional cell-based antagonist competition assay, we show that group B antagonists (AMG6010, capsazepine, and SB-366791) compete with each of the group A antagonists (AMG7472, AMG6880, and BCTC), indicating that proton activation does not alter the capsaicin-binding pocket or the antagonist affinities.

Materials and Methods

Cloning and Stable Transfections. Cloning and stable cell generation for rat and rabbit TRPV1 (and its mutants) were described by Gavva et al. (2004). Chinese hamster ovary (CHO) cells stably expressing TRPV1 were maintained in Dulbecco’s modified Eagle’s medium supplemented with 10% dialyzed fetal bovine serum, 800 μg/ml Geneticin, penicillin, streptomycin, l-glutamine, and nonessential amino acids. Functional TRPV1 channels are present at the plasma membrane, as well as at the intracellular membranes, such as endoplasmic reticulum (Karai et al., 2004). Because we have used agonist-induced 45Ca2+ uptake as the readout, it should be noted that the pharmacology of agonists and antagonists reported in this article is reflecting the activity of the plasma membrane TRPV1 channels.

45Ca2+ Uptake Assay. Two days before the assay, cells were seeded in Cytostar 96-well plates (GE Healthcare, Little Chalfont, Buckinghamshire, UK) at a density of 20,000 cells/well. The activation of TRPV1 is followed as a function of cellular uptake of radioactive calcium (45Ca2+; MP Biomedicals, Irvine, CA). All the 45Ca2+ uptake assays had a final 45Ca2+ concentration at 10 μCi/ml.

Capsaicin Antagonist Assay. Compounds were preincubated with TRPV1 expressing CHO cells in Hanks’ buffered saline solution supplemented with 0.1 mg/ml BSA and 1 mM HEPES at pH 7.4 at room temperature for 2 min before addition of 10 μM capsaicin (final concentration, 0.5 μM) in Ham’s F-12 media and then left for an additional 2 min before compound washout.

Proton Antagonist Assay. Compounds were preincubated with CHO cells expressing TRPV1 at room temperature for 2 min before addition of 10 μM capsaicin in Ham’s F-12 media supplemented with 30 mM HEPES, 30 mM MES, and 0.1 mg/ml BSA adjusted to pH 4.1 with HCl (final assay pH 5) and then left for an additional 2 min before compound washout.

Antagonist Competition Assay. CHO cells expressing rat TRPV1 were incubated with antagonist mixtures for example: 0, 1.1, 3.3, or 10 μM (final concentration) capsazepine combined with each of the 400, 133, 44.3, 14.7, 4.9, 1.65, 0.51, 0.17, 0.056, and 0.014 nM (final concentration) BCTC for 5 min before the addition of 10 μM capsaicin in F12 media supplemented with 30 mM HEPES, 30 mM MES, and 0.1 mg/ml BSA adjusted to pH 4.1 with HCl (final assay pH 5) and then left for an additional 2 min before compound washout.

Compound Washout and Analysis. Assay plates were washed two times with phosphate-buffered saline and 0.1 mg/ml BSA using a plate washer (ELX405; Bio-Tek Instruments, Inc., Winooski, VT) immediately after the functional assay. Radioactivity in the 96-well plates was measured using a MicroBeta Jet (PerkinElmer Life and Analytical Sciences). \( I_{C50} \) and \( pA_2 \) values were calculated by generating antagonist competition curves and Schild plots using Prism 4.01 (GraphPad Software Inc., San Diego, CA).

Reagents. All the cell culture reagents were purchased from Invitrogen (Carlsbad, CA). AMG0610 (Bo et al., 2003), AMG7472

Proton Gating of TRPV1 Does Not Alter Antagonist Affinities

1525
(Balan et al., 2004), and BCTC were synthesized at Amgen Inc. (Thousand Oaks, CA) (>95% purity, NMR, mass, and CHN analysis confirmed). Other reagents were obtained from the following companies: capsaicin from Calbiochem (San Diego, CA), capsazepine and SB-366791 from Tocris Cookson Inc. (Ellisville, MO), and SB-366791 from Sigma (St. Louis, MO). Structures of antagonists used in this study are shown in Fig. 1A.

Results

Characterization of TRPV1 Antagonists in Agonist-Induced $^{45}$Ca$^{2+}$ Uptake Assay. AMG7472, a novel benzimidazole (Balan et al., 2004), is identified as an antagonist of both capsaicin and proton (pH 5) activation of TRPV1, whereas AMG0610 is identified as an antagonist of capsaicin but not proton activation of rat TRPV1 (Fig. 1, B and C). As reported previously, BCTC (Valenzano et al., 2003) and AMG6880 (compound 49b in Doherty et al., 2005) blocked both capsaicin and proton activation, whereas capsazepine (McIntyre et al., 2001) and SB-366791 (Gavva et al., 2005) blocked only capsaicin but not proton activation of rat TRPV1 (Fig. 1, B and C). In fact, at higher concentrations (>0.3 μM), AMG0610 and SB-366791 showed a concentration-dependent potentiation of pH 5-induced $^{45}$Ca$^{2+}$ uptake in CHO cells expressing rat TRPV1 but not in untransfected cells (Fig. 1C; data not shown). In this article, we have defined the compounds that block both capsaicin and proton activation of rat TRPV1 as “group A antagonists” (AMG6880, AMG7472, and BCTC) and those that block capsaicin but not proton activation as “group B antagonists” (AMG0610, capsazepine, and SB-366791).

To determine whether AMG0610, AMG6880, AMG7472, BCTC, capsazepine, and SB-366791 are competitive antagonists at rat TRPV1, we tested concentration-response curves for the induction of $^{45}$Ca$^{2+}$ uptake by capsaicin, as a function of the concentration of above TRPV1 antagonists. For all the antagonists, concentration-response curves for induction of $^{45}$Ca$^{2+}$ uptake in CHO cells expressing rat TRPV1 by capsaicin showed parallel rightward shifts with no depression of the maximum response, indicating competitive antagonism (Fig. 1, D and E; data not shown). The $pA_2$ values determined by Schild analysis are shown in Table 1. The rank order of potency against capsaicin activation is BCTC $\geq$ AMG7472 $> \geq$ AMG6880 $> \geq$ AMG0610 $> \geq$ capsazepine $\geq$ SB-366791.

![Fig. 1. Structures of antagonists used in the study are shown in A. Comparison of antagonists for inhibition of capsaicin (0.5 μM) (B) and proton (pH 5) (C) induced activation of rat TRPV1. CHO cells stably expressing rat TRPV1 were used in agonist-induced $^{45}$Ca$^{2+}$ uptake assay as described under Materials and Methods. Cells were incubated for 2 min with increasing concentrations of antagonists as indicated, followed by the addition of agonists for additional 2 min. Each point in the graph is an average ± S.D. of an experiment conducted in triplicate. Please note potentiation of pH 5-induced $^{45}$Ca$^{2+}$ uptake above 100% by SB-366791 at high concentrations (>10 μM) in C. IC$_{50}$ values for capsaicin and pH 5 activation are shown in Table 2. D, concentration-response curves for capsaicin-induced $^{45}$Ca$^{2+}$ uptake into CHO cells expressing rat TRPV1 in the absence or presence of 1.11, 3.33, or 10 μM capsazepine. E, Schild analysis of the antagonism produced by 1.11 to 10 μM capsazepine.](molpharm.aspetjournals.org)
Molecular Determinants Required for Antagonist Action Are Present in the Transmembrane Domains 3 and 4 Region of TRPV1. Our data and that of other investigators have shown that agonists such as capsaicin, resiniferatoxin, endogenous ligands, as well as antagonists such as BCTC and capsazepine, require the TM3/4 region and Thr\(^{550}\) for their actions at TRPV1 (Jordt and Julius, 2002; Chou et al., 2004; Gavva et al., 2004; Phillips et al., 2004). Because several antagonists used in this study represent novel chemical scaffolds and show differential pharmacology, we have tested their activity at the capsaicin-insensitive rabbit TRPV1 (Gavva et al., 2004) and the capsaicin-sensitive rabbit TRPV1 mutant (I550T) to determine whether the same critical determinants in the TM3/4 region are required for antagonist action. Protons (pH 5) activate both rabbit TRPV1 and rabbit TRPV1-I550T equivalently. We hypothesized that if group A antagonists act through separate sites to block capsaicin and proton activation, and group B antagonists only bind at one site to block capsaicin activation and are unable to bind at a second site that is required for blocking proton activation, then group A, but not group B, antagonists should block proton activation of the capsaicin-insensitive rabbit TRPV1.

All the antagonists tested are ineffective (IC\(_{50}\) > 4000 nM) against blocking proton activation of capsaicin-insensitive rabbit TRPV1 (Table 2). AMG6880, AMG7472, BCTC, and capsazepine blocked both proton and capsaicin activation of the capsaicin-sensitive rabbit TRPV1-I550T mutant, confirming that Thr\(^{550}\) is a critical determinant for antagonist action (Table 2). Capsaicin activation of rabbit TRPV1-I550T was blocked by all TRPV1 antagonists used in this study but not by the P2X\(_{2/3}\) antagonist A-317491 (Jarvis et al., 2002; Table 2) further indicating that all the TRPV1 antagonists require the same critical determinants for blocking both capsaicin and proton activation. The findings (1) group A antagonists tested are ineffective against blocking proton activation of capsaicin-insensitive rabbit TRPV1 (Table 2), 2) group B antagonists neither blocked nor potentiated pH 5 activation of rabbit TRPV1, and 3) both group A and B are antagonists of capsaicin activation of rabbit TRPV1-I550T indicate that all of these antagonists act through the same or an overlapping binding pocket to block both capsaicin and proton activation. The fact that protons activate rabbit TRPV1 and that group A antagonists did not block proton activation of rabbit TRPV1, a channel that lacks an optimal capsaicin-binding pocket, suggests that group A antagonists are non-competitive with respect to proton activation. In addition, concentration response curves for proton activation in the absence or presence of group A antagonists indicated a non-competitive inhibition of proton activation of rat TRPV1 (i.e., curves shifted to the right in a nonparallel fashion with decreasing maximum) (Supplemental Fig. 1).

**Capsazepine and SB-366791 Compete with and Prevent BCTC Antagonism but Not Ruthenium Red Antagonism of Rat TRPV1 Activation by Protons.** Because capsazepine and SB-366791 are competitive antagonists of capsaicin activation and were found to be ineffective at blocking proton (pH 5) activation of rat TRPV1, we investigated the possibility that capsazepine and SB-366791 fail to block proton activation because their affinity to rat TRPV1 is altered by proton activation-induced conformational changes in the capsaicin-binding pocket. We hypothesized that if indeed capsazepine or SB-366791 bind at the same binding pocket as BCTC, and proton activation does not alter the binding pocket, then they should compete with and prevent BCTC antagonism of rat TRPV1 activation by protons. We chose two concentrations of BCTC, one that blocks approximately 50% of pH 5-induced \(^{45}\)Ca\(^{2+}\) uptake (0.5 nM) and a second one that blocks approximately 90% of pH 5-induced \(^{45}\)Ca\(^{2+}\) uptake (2.5 nM). These BCTC concentrations were combined with different concentrations of either capsazepine (200 nM to 40 \(\mu\)M) or SB-366791 (200 nM to 40 \(\mu\)M), and the concentration-response relationship was determined in capsaicin- and pH 5-induced \(^{45}\)Ca\(^{2+}\) uptake assays (Fig. 2).

As expected for additive antagonism, both capsazepine and SB-366791 blocked the remaining capsaicin-induced \(^{45}\)Ca\(^{2+}\) uptake in the presence of BCTC (0.5 nM) in a concentration-dependent manner (Fig. 2, A and B). Remarkably, when activating with protons, both capsazepine and SB-366791

prevented BCTC antagonism of rat TRPV1, as seen by a concentration-dependent increase of pH 5-induced \(^{45}\text{Ca}^{2+}\) uptake in the presence of BCTC (Fig. 2, C and D). These findings indicate that both capsazepine and SB-366791 compete with BCTC for binding to rat TRPV1 under low pH conditions but do not block proton activation, and they support the hypothesis that proton activation does not alter the capsaicin-binding pocket of rat TRPV1.

Both capsazepine and SB-366791 showed additive antagonism with ruthenium red, a pore blocker, at blocking rat TRPV1 activation by capsaicin, but they did not prevent ruthenium red antagonism of proton activation (Fig. 2, E and F). As expected, this indicates that ruthenium red and capsazepine/SB-366791 do not compete at the same binding pocket.

**Capsazepine and SB-366791 Prevention of BCTC Antagonism Is Competitive.** Capsazepine and SB-366791 were able to prevent BCTC antagonism of rat TRPV1 activation by protons, suggesting that they bind at the same site as BCTC under low pH conditions (pH 5). To clarify whether the mechanism of capsazepine and SB-366791 prevention of BCTC antagonism is competitive or noncompetitive, we tested the concentration-response curve of BCTC antagonism of rat TRPV1 activation by protons in the absence or presence of different concentrations of either capsazepine or SB-366791 (Fig. 3, A–D). As expected for compounds competing at the same binding pocket, capsazepine and SB-366791 caused parallel rightward shifts in the BCTC concentration-response (inhibition) curve; i.e., more BCTC was required to show the same level of inhibition in the presence of capsazepine or SB-366791. IC\(_{50}\) values for BCTC alone, or in the presence of 1.1, 3.3, and 10 \(\mu\)M capsazepine, were 0.36, 1.1, 2.9, and 13 nM, respectively (Fig. 3A). Schild analysis determined a \(\rho_A\) value of 6.2 with a slope of 1.26 for capsazepine at the BCTC binding site (Fig. 3B). IC\(_{50}\) values for BCTC alone, or in the presence of 10, 18, and 18 \(\mu\)M SB-366791 were 2.9, 5.9, and 22.9 nM, respectively (Fig. 3C). Schild analysis gave a \(\rho_A\) value of 6.26 with a slope of 1.02 for SB-366791 at the BCTC binding site (Fig. 3D). Both capsazepine and SB-366791 had no effect on the concentration-response curve for inhibition by ruthenium red (Fig. 3E and data not shown). An unrelated compound, A-317491 (a selective P2X\(_{2/3}\) antagonist; Jarvis et al., 2002), showed no effect on either BCTC or ruthenium red antagonism of TRPV1 activation by protons (Fig. 3F and data not shown).

**Antagonists from Different Chemical Scaffolds Compete at the Same Binding Pocket.** Capsazepine, SB-366791, and BCTC belong to different chemical scaffolds yet

![Fig. 2](https://example.com/fig2.png)

**Fig. 2.** Concentration-dependent inhibition of capsaicin activation by mixtures of capsazepine and BCTC (A) or SB-366791 and BCTC (B) or capsazepine and ruthenium red (RR) (E). Note the remaining capsaicin-induced \(^{45}\text{Ca}^{2+}\) uptake in the presence of BCTC (0.5 nM) or 150 nM RR inhibition was inhibited in a concentration-dependent manner by capsazepine and SB-366791, indicating additive antagonism. Capsazepine (C) and SB-366791 (D) compete with BCTC and prevent BCTC inhibition of rat TRPV1 activation by protons. Note that BCTC inhibition of proton-induced \(^{45}\text{Ca}^{2+}\) uptake is prevented in a concentration-dependent manner by both capsazepine and SB-366791 (C and D); however, capsazepine did not affect RR inhibition of proton-induced \(^{45}\text{Ca}^{2+}\) uptake (F). IC\(_{50}\) values for capsazepine and SB-366791 blockade of 2.5 nM BCTC inhibition of rat TRPV1 activation by protons are 0.55 ± 0.07 and 1.15 ± 0.09 nM, respectively. At higher concentrations (>0.3 \(\mu\)M), SB-366791 potentiation is represented by an increase of \(^{45}\text{Ca}^{2+}\) uptake above 100% (D).
compete for binding at the capsaicin-binding pocket of rat TRPV1 in a pH-independent manner, suggesting that proton activation does not alter the binding pocket (Figs. 1–3). To extend this observation to other chemical scaffolds, we have conducted antagonist competition experiments with each of the group A antagonists against each of the group B antagonists. First, we tested the ability of AMG0610 to compete with and prevent AMG6880, AMG7472, and BCTC antagonism of rat TRPV1 activation by protons. As expected for compounds competing at the same binding pocket, AMG0610 caused parallel rightward shifts in the inhibition curves of each of the group A antagonist (Fig. 4; Table 3). Likewise, all group B antagonists competed with and caused parallel rightward shifts in each of the group A antagonist concentration-response inhibition curves of rat TRPV1 activation by protons, indicating that all of these antagonists compete with each other at the same binding pocket at pH 5 (Fig. 4, and data not shown). The $pA_2$ values determined by Schild analysis for each of the group B antagonists are shown in Table 3.

**Discussion**

By using agonist-induced $^{45}$Ca$^{2+}$ uptake and CHO cells stably expressing rat TRPV1, we have characterized AMG0610 and AMG7472 as novel TRPV1 antagonists; confirmed the pharmacology of AMG6880, BCTC, and capsazepine; and shown that all antagonists are competitive against capsaicin activation. Group A antagonists (AMG6880, AMG7472, and BCTC) blocked both capsaicin and proton activation, whereas group B antagonists (AMG0610, capsazepine, and SB-366791) blocked capsaicin, but not proton, activation of rat TRPV1. TRPV1 antagonists that block all modes of activation of rat (AMG9810, A-425619, BCTC) or guinea pig (capsazepine) TRPV1 showed efficacy in rat and guinea pig models of inflammatory pain, respectively (Pomonis et al., 2003; Walker et al., 2003; Gavva et al., 2005; Honore et al., 2005). Because antagonism of all modes of TRPV1 activation seems to correlate with anti-hyperalgesic effects in vivo, antagonists such as AMG6880, AMG7472, and BCTC may help define the role of TRPV1 in pain and other disease states.

It should be noted that SB-366791 was reported to be an antagonist of both capsaicin and proton activation of rat and human TRPV1 in electrophysiological studies using transfected human embryonic kidney 293 cells (Gunthorpe et al., 2004). However, in $^{45}$Ca$^{2+}$ uptake assays using CHO cells, we have previously shown that SB-366791 is an antagonist of capsaicin activation of both rat and human TRPV1 but is ineffective (IC$_{50}$ >40 μM) against proton (pH 5) activation of both rat and human TRPV1 (Gavva et al., 2005). The key differences between these two studies are: 1) nontransfected human embryonic kidney 293 cells show proton-activated currents, whereas CHO cells show no proton-activated $^{45}$Ca$^{2+}$ uptake, 2) electrophysiological assays are conducted in the absence of extracellular calcium that eliminates calcium-dependent desensitization of the TRPV1 channels, whereas
$^{45}\text{Ca}^{2+}$ uptake assays are conducted in the presence of extracellular calcium at a final concentration of 1 mM, which represents a more physiological environment compared with electrophysiological studies, and 3) potentiation of rat TRPV1 activation by protons observed in CHO cells may not be observed in electrophysiological assays if it occurs by delaying calcium-dependent desensitization. Further studies should clarify the role of cell background and differences in antagonist pharmacology in electrophysiological versus $^{45}\text{Ca}^{2+}$ uptake assays. In addition, careful examination of the cDNA sequences used by different groups for the presence of single nucleotide polymorphisms in TRPV1 and their role in agonist and antagonist sensitivity should help the observed conflicting results using TRPV1 antagonists such as capsazepine (McIntyre et al., 2001; Seabrook et al., 2002), iodoresiniferatoxin (Seabrook et al., 2002; Shimizu et al., 2005), and SB-366791 (Gunthorpe et al., 2004; Gavva et al., 2005).

Using chimeric domain swap analysis between capsaicin-sensitive TRPV1 and capsaicin-insensitive TRPV1 (Jordt and Julius, 2002; Gavva et al., 2004), it was shown that vanilloid sensitivity and $[^3\text{H}]$resiniferatoxin binding are transferable with the TM3/4 region, suggesting that the TM3/4 region constitutes the vanilloid binding pocket. Furthermore, mutagenesis studies within the TM3/4 region identified several key molecular determinants for both agonist and antagonist actions (Jordt and Julius, 2002; Chou et al., 2004; Gavva et al., 2004; Phillips et al., 2004) and led to the proposed models of the vanilloid-binding pocket (Jordt and Julius, 2002; Chou et al., 2004; Gavva et al., 2004).

We hypothesized that if group B antagonists bind at the same site as group A antagonists on rat TRPV1, and proton activation does not alter the capsaicin-binding pocket, then they should be able to compete with and prevent group A antagonism of rat TRPV1 activation by protons. We have shown that group B antagonists act additively with group A antagonists to block capsaicin activation. It is remarkable that each of the group B antagonists prevented all of the group A antagonists from blocking proton activation of rat TRPV1, indicating specific competition between group A and B antagonists at pH 5. This proves unequivocally that group B antagonists bind rat TRPV1 at pH 5 with similar affinity as at pH 7.2 during capsaicin activation (compare $p_{A_2}$ values in Table 1 and 3) but that they are ineffective against blocking proton activation. It also confirms that all antagonists (group A and B) interact at the same or an overlapping binding pocket. Finally, it suggests that proton activation neither alters the capsaicin-binding pocket nor affects antagonist affinity at the capsaicin-binding pocket. The $p_{A_2}$ values of each of the three group B antagonists at each of the group

![Fig. 4](image-url)
A antagonist binding sites are similar (Table 3), further showing that indeed all these antagonists bind to the same pocket, and their affinities are not altered by proton activation of TRPV1. These results also suggest that acidification does not affect group B antagonists and their ability to bind rat TRPV1. Furthermore, calculated pK\text{a} values suggest that acidification may not affect group B antagonists (data not shown). None of the group B antagonists competed with or affected ruthenium red inhibition of TRPV1, indicating that there is no overlap in the binding pocket for competitive antagonists (group A and B) and the pore blocker, ruthenium red.

We propose that both agonists and antagonists share the same binding pocket (Fig. 5) and that proton activation does not alter the conformation of the binding pocket based on 1) the competitive antagonism of capsaicin activation by all of these antagonists (Valenzano et al., 2003; Gunthorpe et al., 2004; current study), 2) the requirement of the same critical determinants for actions of all antagonists (Gavva et al., 2004; current study), 3) the ability of AMG6610, capsazepine, and SB-366791 to compete with each of the group A antagonists, and 4) the similarity of pA\text{a} values of group B antagonists at the capsaicin-binding pocket at pH 7.2 (capsaicin activation) and pH 5 (proton activation). Because the critical molecular determinants for capsaicin or vanilloid interaction (Jordt and Julius, 2002; Gavva et al., 2004) and proton activation (Jordt et al., 2000) have been reported to be different, agonism of TRPV1 by protons should be considered allosteric to the capsaicin site. The ability to block proton activation of TRPV1 by competitive antagonists that interact at the capsaicin-binding pocket occurs perhaps by locking the channel conformation in a nonconducting state. We propose that these antagonists should be defined as allosteric inhibitors for proton activation. For example, group A antagonists are competitive antagonists at the capsaicin-binding pocket and allosteric inhibitors for proton activation, whereas group B antagonists are just competitive antagonists at the capsaicin binding pocket of TRPV1 (Fig. 5). No allosteric inhibition of proton activation by protons was seen with group B antagonists, even though they bind to TRPV1 in the same binding pocket as group A antagonists (Fig. 5). Based on these observations, we propose that group A antagonists stabilize or lock the channel conformation in a closed or nonconductive state when they interact at the capsaicin binding pocket, whereas group B antagonists only act as true competitive antagonists at the capsaicin binding pocket but do not lock or stabilize the nonconducting state of the channel.

It is noteworthy that all TRPV1 antagonists reported thus far seem to bind at the capsaicin site (competitive antagonists of capsaicin activation), and based on their ability to lock or stabilize the channel conformation, some are able to block all modes of activation. Other than the nonselective pore blocker ruthenium red, compounds that block all modes of TRPV1 activation via interaction at a site outside of the capsaicin-binding pocket have not been identified yet. The trialkylglycine-based compounds DD161515 and DD191515 have been reported as noncompetitive antagonists of capsaicin activation that may act through a different site than capsaicin (Garcia-Martinez et al., 2002). However, whether these molecules block all modes of TRPV1 activation remains unknown. Ruthenium red seems to block all modes of TRPV1 activation by interacting with the residues in the channel pore (Garcia-Martinez et al., 2000).

It is interesting that capsazepine, although classified as a group B antagonist at rat TRPV1, acts as a group A antagonist at human and guinea pig TRPV1 as well as the capsaicin-sensitive rabbit TRPV1 mutant, I550T; i.e., capsazepine blocks proton activation of these channels (McIntyre et al.,...
capsazepine is a weak antagonist of capsaicin activation of rat TRPV1 (Shimizu et al., 2005). Capsazepine may act as antihyperalgesics in humans because they are potent antagonists at all modes of human TRPV1.

The ability to block proton activation of TRPV1 by capsaze-

pene requires Leu447, because replacement of Leu447 with Met447 in the capsaicin-sensitive rabbit TRPV1 mutant (rab-

bit TRPV1-1550T; Gaava et al., 2004) or in human TRPV1 (Phillips et al., 2004) resulted in capsazepine’s being ineffec-
tive against proton activation. Conversely, mutations in the TM3/4 region of rat TRPV1 to the corresponding human TRPV1 residue (IS41M, V516L, and M547L) enabled capsaze-
pine inhibition of proton activation at a level similar to that observed in human TRPV1 (Phillips et al., 2004). AMG6880 and AMG9810 block proton activation of TRPV1 with either Leu447 (human TRPV1 and rabbit TRPV1-1550T) or Met447 (rat TRPV1), whereas AMG6061 and SB-366791 are ineffect-

ive against blocking proton activation of TRPV1 with either Leu447 (human TRPV1 and rabbit TRPV1-1550T) or Met447 (rat TRPV1; Table 2, Gaava et al., 2005, and data not shown). These studies indicate that a single residue within the cap-
saicin-binding pocket can differentially affect the ability of TRPV1 antagonists to lock or stabilize the channel confor-
mation in the closed state. The mechanisms of action for blocking all modes of TRPV1 activation seems to be more complex because molecules interacting at the capsaicin-binding pocket act either as agonists, potentiat-
ors of proton activation, or antagonists for some or all modes of activation. For example, some group B antagonists, such as AMG-0610, SB-

366791 (Fig. 1C), and KjM429 (Wang et al., 2002), act as potenti-
ators of proton activation of TRPV1, probably by increasing the open channel conformation or by delaying desensitization of the TRPV1 channel. Still to be determined are the precise interactions of specific residues within the capsaicin-binding pocket with different antagonists and their role in locking or stabilizing the channel conformation in the closed or nonconducting state and/or interfering with the inactivation and/or desensitization of TRPV1.
