ABSTRACT

We investigated the action of 1α,25-dihydroxyvitamin D₃ [1α,25(OH)₂D₃], a novel Gemini vitamin D₃ analog Ro-438-3582 [1α,25-dihydroxy-20S-21(3-hydroxy-3-methyl-butyl)-23-yn-26,27-hexafluorocholecalciferol (Ro3582)], and a classic vitamin D₃ analog Ro-26-2198 [1α,25-dihydroxy-16,23(Z)-diene-26,27-hexafluoro-19-nor-cholecalciferol (Ro2198)] in modulating the transforming growth factor-β (TGF-β/bone morphogenetic protein (BMP) system in MCF10 immortalized breast epithelial cells. We found that 1α,25(OH)₂D₃, Ro3582, and Ro2198 all enhanced BMP/Smad signaling by increasing the phosphorylation of receptor-regulated Smads. Ro3582 was more active than Ro2198, but both were considerably more active than 1α,25(OH)₂D₃. Ro3582 enhanced BMP/Smad signaling by 1) inducing the phosphorylation of receptor-regulated Smads (Smad1/5), 2) increasing the accumulation of phosphorylated Smad1/5 in the nucleus, and 3) activating BMP-mediated transcription in MCF10 breast epithelial cells. Furthermore, Ro3582 induced the synthesis of BMP-2 and BMP-6 mRNA and protein, and the expression of Smad6 mRNA in MCF10 breast epithelial cells was inhibited by Ro3582. The induction of phospho-Smad1/5 by Ro3582 was inhibited by treatment with the BMP antagonist Noggin, whereas neutralizing antibody to TGF-β did not block the induction of phospho-Smad1/5 by Ro3582. Treatment with Noggin also blocked the effect of Ro3582 on nuclear accumulation of phospho-Smad1/5 and the induction of BMP-2 and BMP-6 mRNA synthesis. These results indicate that the activation of BMP/Smad signaling by the Gemini vitamin D₃ analog Ro3582 may be through the production of BMP ligands, including BMP-2 and BMP-6, and/or down-regulation of the inhibitory Smad6. This is the first report to show that 1α,25(OH)₂D₃ and its derivatives activate BMP/Smad-specific signaling in human breast epithelial cells.

The transforming growth factor-β (TGF-β) superfamily, including TGF-βs, activins, and bone morphogenetic proteins (BMPs), are multifunctional cytokines that affect inflammation, immune responses, cell growth, differentiation, apoptosis, development, and carcinogenesis (Ten Dijke et al., 2002; Derynck and Zhang, 2003). BMPs are members of the TGF-β superfamily regulating a large variety of biological responses in many different cells and tissues during embryonic development and postnatal life (Kawabata et al., 1998; Miyazono et al., 2005). BMPs exert their biological effects via binding to two types of serine/threonine kinase BMP receptors, activation of which leads to phosphorylation and translocation into the nucleus of intracellular signaling molecules, including Smad1, Smad5, and Smad8 (Kawabata et al., 1998). Upon BMP receptor activation, the BMP receptor-regulated Smads are phosphorylated in the C-terminal of the MH2 domain and recruit the common partner Smad, Smad4, to the nucleus to mediate BMP-dependent target gene expression (Kawabata et al., 1998; Miyazawa et al., 2002; Miyazono et al., 2005). Although BMPs belong to the TGF-β family and mainly

ABBREVIATIONS: TGF-β, transforming growth factor-β; BMP, bone morphogenetic protein; R-Smad, receptor-regulated Smad; VDR, vitamin D receptor; DMSO, dimethyl sulfoxide; DMEM, Dulbecco’s modified Eagle’s medium; p-, phosphorylated; DAPI, 4,6-diamidino-2-phenylindole; GAPDH, glyceraldehyde-3-phosphate dehydrogenase; BSA, bovine serum albumin; PBS, phosphate-buffered saline; Ro3582, Ro-438-3582, 1α,25-dihydroxy-20S-21(3-hydroxy-3-methyl-butyl)-23-yn-26,27-hexafluorocholecalciferol; Ro2198, Ro-26-2198, 1α,25-dihydroxy-16,23(Z)-diene-26,27-hexafluoro-19-nor-cholecalciferol; 1α,25(OH)₂D₃, 1α,25-dihydroxyvitamin D₃.
have been known to stimulate bone formation, they are now identified as multifunctional molecules regulating growth, differentiation, and apoptosis in many target cells. The biological effects and mechanisms by which BMPs function in breast cancer cells have not been well defined. It is noteworthy that BMPs are known to play roles as potent growth inhibitors in many epithelial cells (Ghosh-Choudhury et al., 2000; Pardali et al., 2005). This growth inhibition is lost with mutations and the associated loss of expression of genes for molecules of the BMP signaling pathway, which results in uncontrolled cell growth with tumor formation, suggesting the possible role of BMP as a tumor suppressor (Haramis et al., 2004; He et al., 2004; Horvath et al., 2004). BMP-2 induces cyclin kinase inhibitor p21 and hypophosphorylation of retinoblastoma protein in estradiol-treated MCF-7 human breast cancer cells (Ghosh-Choudhury et al., 2000). The mechanism of BMP-induced p21 promoter activation involves BMP receptors and BMP Smads (Pouliot and Labrie, 2002). In addition, it has been shown that up-regulation of BMP signaling is associated with the inhibition of proliferation and in vivo tumor growth of androgen-insensitive prostate carcinoma cells (Miyazaki et al., 2004). However, it has also been reported that the BMP/Smad pathway is activated in breast cancer and may contribute to breast cancer progression and dedifferentiation in estrogen receptor-positive breast cancer (Helms et al., 2005).

The hormonally active metabolite of vitamin D₃, 1α,25(OH)₂D₃, functions in the maintenance of calcium homeostasis through the regulation of genes in the intestine, kidney, and bone, and it also controls immune cells and hormone secretion (Sutton and MacDonald, 2003). Nuclear receptor ligands, such as retinoic acid or vitamin D₃ analogs, have been shown to induce the synthesis of ligands and receptors for both TGF-β and BMP in many epithelial cell lines and in myeloid leukemia cells (Falk et al., 1991; Koli and Keski-Oja, 1995; Hatakeyama et al., 1996). Among the studies with TGF-β/BMP signaling and nuclear receptors, 1α,25(OH)₂D₃ has been shown to induce an interaction with intracellular effectors of TGF-β, the Smad3/4 complex, and the vitamin D receptor (VDR) in the nucleus and to potentiate VDR-dependent transcription (Yanagi et al., 1999; Yanagisawa et al., 1999). Because BMP signaling is known to be involved in bone formation and bone metastasis from breast cancer (Reinholz et al., 2002; Helms et al., 2005; Raida et al., 2005), it is of great interest to investigate the role of vitamin D derivatives for the activation of the BMP system and its further downstream signaling in breast cancer.

In the present study, we focused on studying the effects of 1α,25(OH)₂D₃, the classic vitamin D₃ analog Ro2198, and the novel Gemini analog Ro3582 (Fig. 1) in modulating TGF-β/BMP signaling in a breast epithelial cell line. Among many vitamin D analogs we have tested, we selected two synthetic vitamin D analogs, Ro2198 and Ro3582, to investigate their activity in enhancing BMP signaling. Although Ro2198 has potent antiproliferative activity, this analog is not optimal for in vivo studies because of its hypercalcemic toxicity. The novel Gemini analog Ro3582 has a distinctive chemical structure with two bulky side chains that may contribute to its very low hypercalcemic effect. Gemini analogs showed markedly enhanced potency with low hypercalcemic toxicity compared with 1α,25(OH)₂D₃, possibly because of different properties of the liganded VDR facilitating selectivity of cofactor binding and selectively modulating levels of transcription (Uskokovic et al., 2001; Weyts et al., 2004). We investigated the action of synthetic vitamin D₃ analogs in modulating the TGF-β/BMP signaling in MCF10 immortalized breast epithelial cells. The MCF10 human breast epithelial cell lines were established from an immortalized normal MCF10A cell line originally derived from benign breast tissue from a woman with fibrocystic disease (Miller, 2000). The series of MCF10 cell lines was established by transfecting MCF10A normal breast epithelial cells with H-ras (MCF10AT1) and subsequently selecting by growth for several generations in mice (MCF10DCIS.com and MCF10CA1a) (Santner et al., 2001). This series of MCF10 cell lines provides a unique progressive breast cancer model with different stages of progression, such as MCF10A (immortalized), MCF10AT1 (premalignant), MCF10DCIS.com (invasive potential), and MCF10CA1a (malignant, metastatic) cell lines (Miller, 2000; Santner et al., 2001; Tang et al., 2003; Tian et al., 2003). The late-stage metastatic MCF10CA1a cells are resistant to TGF-β-induced growth inhibition, whereas premalignant MCF10AT1 cells are still responsive to TGF-β for growth inhibition (Santner et al., 2001; Tang et al., 2003).

In this report, we examined the effects of classic vitamin D₃ analogs and a novel Gemini analog on the activation of Smad...
signaling and TGF-β/BMP-induced transcriptional activation in MCF10AT1 breast epithelial cells. We report here on the ability of the vitamin D₃ analogs to activate BMP signaling by 1) inducing the phosphorylation of Smads 1/5, 2) increasing its localization in the nucleus, 3) enhancing BMP/Smad-mediated transcription, and 4) increasing synthesis of BMP-2 and BMP-6 mRNAs and proteins in MCF10 breast epithelial cells. This is the first study to show that vitamin D₃ analogs activate BMP/Smad signaling in breast epithelial cells.

Materials and Methods

Reagents. All vitamin D₃ analogs, including 1α,25-dihydroxyvitamin D₃, Ro-26-2198 (Ro2198), and Ro-438-3582 (Ro3582) (>95% purity), were synthesized and provided by Dr. Milan Uskokovic at Hoffmann-La Roche Inc. (Nutley, NJ). BMP-2 (>95% purity), BMP-6 (>95% purity), and Noggin (>90% purity) were obtained from R&D systems (Minneapolis, MN). TGF-β1 and monoclonal anti-TGF-β1, -β2, and -β3 (clone ID11) were obtained from R&D systems. Fugene6 and okadaic acid were obtained from Roche Diagnostics (Indianapolis, IN) and Sigma (St. Louis, MO), respectively. All vitamin D₃ analogs were dissolved in dimethyl sulfoxide (DMSO) before the addition to cell cultures; final concentrations of DMSO were 0.1% or less. Controls with DMSO alone were run in all cases.

Cell Culture. Human breast MCF10AT1 cell line was developed and provided by Dr. Fred Miller’s group at the Barbara Ann Karmanos Cancer Institute (Detroit, MI). MCF10AT1 cells were grown in complete media (DMEM/Ham’s F-12 medium supplemented with 5% horse serum, 1% penicillin/streptomycin, 10 μg/ml insulin, 20 ng/ml epidermal growth factor, 0.5 μg/ml hydrocortisone, and 100 ng/ml cholera toxin) at 37°C in 5% CO₂.

Western Blot Analysis. These procedures have been described previously (Suh et al., 1998). The primary antibodies against VDR (Affinity BioReagents, Golden, CO), actin (Sigma), phosho-Smad3 (Cell Signaling Technology Inc., Beverly, MA), phospho-Smad2 (Chemicon Inc., Temecula, CA), Smad2 (BD Biosciences, San Jose, CA), phospho-Smad1/5/8 (Cell Signaling Technology), Smad3 (Zymed Laboratories, South San Francisco, CA), Smad4 (Santa Cruz Biotechnology, Santa Cruz, CA), and secondary antibodies (Santa Cruz Biotechnology) were used. Cells were treated with test compounds and were harvested at the time indicated in the figure legends.

Quantitative Reverse Transcription-Polymerase Chain Reaction Analysis. Total RNA was isolated from cultured cells using the TRIzol method from Invitrogen (Carlsbad, CA). One microgram of total RNA was reverse-transcribed to cDNA using the random primers and the High Capacity cDNA Archive Kit (Applied Biosystems, Foster City, CA) in a 96-well format. The cDNA was analyzed using the ABI Prism 7000 SDS software (Applied Biosystems). The conditions were as follows: 1 cycle of 95°C for 2 min, 1 cycle of 95°C for 10 min, 40 cycles of 95°C for 15 s, and 60°C for 1 min. Labeled primers for BMP-2, BMP-6, Smad6, and GAPDH were obtained from Applied Biosystems.

Immunoblot for BMP-2 and BMP-6. MCF10AT1 cells were plated in a 100-mm dish and were starved for 24 h in serum-free DMEM/Ham’s F-12 medium. Then, cells were incubated with the vitamin D analog Ro3582 (1 and 10 nM) in 0.1% BSA/DMEM/Ham’s F-12 medium for 48 h. The supernatant was collected and stored as aliquots at −20°C. The supernatant was concentrated by using Amicon Bioseparations Centricon YM-10 from Millipore Corporation (Bedford, MA) for 90 min. The BMP-2 and BMP-6 protein secreted into cell culture supernates was detected by Quantikine BMP-2 immunoassay and DuoSet Human BMP-6 from R&D systems, according to the manufacturer’s instructions.

Plasmids and Transfection Assays. 3GC2-Lux (Ishida et al., 2000) was provided by Dr. Kohei Miyazono (The University of Tokyo, Tokyo, Japan); pCMV-β-gal was provided by Dr. David Mangelsdorf (University of Texas Southwestern Medical School at Dallas, Dallas, TX). For transient transfection assays, cells (40,000 cells/well in 24-well plates) were plated and transfected with a total of 200 ng of DNA vectors, such as 3GC2-Lux (100 ng/well) or pCMV-β-gal (50 ng). Cells were transfected using Fugene6 in serum-free medium for 6 h and then replaced with fresh medium (0.1% BSA/DMEM) with test compounds, as published previously (Suh et al., 2003). Twenty-four hours later, cells were washed with PBS and lysed with 100 μl of 1X reporter lysis buffer (Promega, Madison, WI). Luciferase values were analyzed using Veritas Microplate Luminometer (Turner Biosystems, Sunnyvale, CA) and normalized for β-galactosidase activity.

Phosphatase Assay. The serine/threonine phosphatase assay was performed according to the manufacturer’s instructions (Promega). In brief, MCF10AT1 cells were grown in growth medium to subconfluence, collected, centrifuged, and homogenized in cell extraction buffer (50 mM Tris-HCl, pH 7.0, 0.1% (v/v) β-mercaptoethanol, 0.1 mM EDTA, 0.1 mM EGTA, 25 μg/ml leupeptin, and 25 mg/ml aprotinin) on ice for 30 s. The homogenized lysate was centrifuged at 100,000g at 4°C for 1 h, and endogenous inorganic phosphate from the supernatant was removed using a Sephadex G-25 resin column. Test compounds were then added to the cell lysate, incubated for 10 min at 30°C, mixed with molybdate dye/additive solution, and inorganic phosphate was determined by measuring the absorbance at 595 nm.

Fluorescence Microscopy. Plates were coated with poly(1-lysine) (0.1 mg/ml) overnight at 37°C. Then, cells (30–50% confluent) were plated in the appropriate medium as indicated. After incubation of cells with compounds for 24 h, cells were fixed in 4% paraformaldehyde (1X PBS, pH 7.4) for 20 min at room temperature. Cells were then washed with PBS twice and blocked for 1 h with 10% bovine serum albumin/0.5% Triton-X1% PBS solution. The primary antibody solution (1:100 dilution for phospho-Smad1/5) was added to the plates, and the cells were incubated at 4°C overnight or for 3 h at room temperature. The cells were then washed with PBS for 5 to 10 min. Fluorophore-conjugated secondary antibody (1:200 dilution, Alexa Fluor 488 goat anti-rabbit IgG; Invitrogen) against the species of the primary antibody was added to the cells and incubated for 1 to 2 h at room temperature. The cells were washed 1X PBS three times for 15 min and were irradiated with a green laser (488 nm). Fluorescence was viewed with a microscope. For DAPI staining, plain UV light (364 nm) was used.

Statistical Analysis. The statistical analysis was performed using the Student’s t test.

Results

Phosphorylation of Smad1/5 Is Increased by Vitamin D₃ Analogs in MCF10AT1 Breast Epithelial Cells. Because TGF-β/BMP signal transduction is mediated by Smad proteins, we first evaluated the effects of 1α,25(OH)₂D₃ and vitamin D₃ analogs on the activation of Smad signaling. Receptor-regulated Smads (R-Smads), Smad2 or Smad3, are phosphorylated by the TGF-β type I receptor kinase, whereas Smad2 is also activated by the activin receptor. Other R-Smads, such as Smad1, Smad5, and Smad8, are phosphorylated by the BMP receptor kinase. Once R-Smads are activated by receptor kinases, they can form a heteromeric complex with the common partner Smad, Smad4, and the complex is then translocated into the nucleus to induce transcriptional activation of TGF-β, activin, or BMP-specific genes. In our study on the effect of vitamin D₃ analogs on...
Smad signaling, we treated MCF10AT1 cells for 24 h before harvest. For the BMP pathway, a single antibody that recognizes pSmad1(Ser463/465), pSmad5(Ser463/465), and pSmad8(Ser426/428) was used. All three of these Smads are direct targets of the BMP receptor kinase-mediated pathway. Therefore, measuring the phosphorylation of Smads1, -5, and/or -8 together (Smad1/5/8) with a single antibody provides a measure of the activity of the BMP receptor kinase-mediated pathway. In the present study, the antibody for Smad1, -5, and/or -8 is measuring Smad1/5 because Smad8 has a different mobility on SDS gels. We found that treatment of MCF10AT1 cells with synthetic vitamin D₃ analogs Ro2198 and Ro3582 had marked stimulatory effects on the phosphorylation of Smad1/5 at 24 h that was dose-dependent (Fig. 2A). Both synthetic vitamin D₃ analogs caused a strong induction of phospho-Smad1/5 at 0.1, 1, and 10 nM, whereas the naturally occurring and active metabolite, 1α,25(OH)₂D₃, had a small increase at 10 nM (Fig. 2A). Furthermore, Ro3582 began to induce phosphorylation of Smad1/5 at 12 h, and the effect was much stronger at 24 h (Fig. 2B). Activation of Smad2 or Smad3 was also measured with an antibody that recognizes phospho-Smad2 (serines 465 and 467) or an antibody to phospho-Smad3 (serines 433 and 435). Both phosphorylation sites in Smad2 and Smad3 are direct targets of the TGF-β type I receptor kinase. Using antibodies to Smad1/5 and Smad2/3, we determined that the vitamin D₃ analogs induced the phosphorylation of BMP R-Smads, Smad1/5, but not the phosphorylation of Smad2 or Smad3 (TGF-β/activin R-Smads), in MCF10AT1 cells (data not shown).

Up-Regulation of BMP Signaling by the Vitamin D₃ Analog Ro3582 Is Not Blocked by TGF-β Neutralizing Antibody but by a BMP Antagonist, Noggin. As shown in Fig. 3A, we used the TGF-β antibody (1D-11) to determine whether the effects of Ro3582 are mediated by an increase in TGF-β synthesis in MCF10AT1 breast epithelial cells. The antibody to phospho-Smad3 used (Cell Signaling Technology) recognizes both phospho-Smad3 (lower band) and phospho-Smad1/5 (upper band). The phosphorylation of Smad3 was induced by TGF-β₁ (1 ng/ml), which is blocked by TGF-β neutralizing antibody (1D11, 50 μg/ml). However, we show here that the induction of the phospho-Smad1/5 by the vitamin D₃ analog Ro3582 (10 nM) or BMP-2 (100 ng/ml) is not blocked by the neutralizing antibody to TGF-β₁. This suggests that the phosphorylation of Smad1/5 is not mediated by an effect of the vitamin D₃ analog on stimulating the synthesis of TGF-β₁ or to activate the TGF-β system. More importantly, we evaluated the effect of a specific antagonist of BMP, Noggin, to determine whether a BMP antagonist blocks the action of vitamin D derivatives. As shown in Fig. 3B, the phosphorylation of Smad1/5 induced by the vitamin D₃ analog Ro3582 (10 nM) or BMP-2 (100 ng/ml) was inhibited by the antagonist Noggin (+, 60 ng/ml; ++, 300 ng/ml). In contrast, the induction of phospho-Smad3 (lower band) by TGF-β₁ (1 ng/ml) was not blocked by Noggin, whereas the

**Fig. 2.** Up-regulation of BMP signaling by 1α,25-dihydroxyvitamin D₃ and vitamin D₃ analogs in MCF10AT1 breast epithelial cells. A, MCF10AT1 cells (5 × 10⁵ cells/six-well plate) were starved for 24 h in serum-free DMEM/Ham’s F-12 medium. Then cells were incubated with DMSO, 1α,25(OH)₂D₃, Ro2198, or Ro3582 (0.1, 1, and 10 nM) in 0.1% BSA/DMEM/Ham’s F-12 medium for 24 h. Up-regulation of the phospho-Smad1/5 by vitamin D₃ analogs is shown. B, MCF10AT1 cells (5 × 10⁵ cells/six-well plate) were starved for 24 h in serum-free DMEM/Ham’s F-12 medium. Then cells were incubated with DMSO or Ro3582 (10 nM) in 0.1% BSA/DMEM/Ham’s F-12 medium for 6, 12, and 24 h. The phosphorylation of Smad1/5 was up-regulated by Ro3582 in a time-dependent manner.

---

**Fig. 3.** The phosphorylation of Smad1/5 induced by the novel vitamin D₃ analog Ro3582 is not blocked by TGF-β neutralizing antibody but by a BMP antagonist, Noggin. A, MCF10AT1 cells (5 × 10⁵ cells/six-well plate) were starved for 24 h in serum-free DMEM/Ham’s F-12 medium. Then cells were incubated with the indicated compounds in 0.1% BSA/DMEM/Ham’s F-12 medium for 24 h. The phosphorylation of Smad1/5 induced by TGF-β₁ (1 ng/ml), which is blocked by TGF-β neutralizing antibody (1D11, 50 μg/ml). The induction of the phospho-Smad1/5 by vitamin D₃ analog Ro3582 (10 nM) or BMP-2 (100 ng/ml) is not blocked by the neutralizing antibody to TGF-β₁. This suggests that the phosphorylation of Smad1/5 is not mediated by an effect of the vitamin D₃ analog on stimulating the synthesis of TGF-β₁ or to activate the TGF-β system. More importantly, we evaluated the effect of a specific antagonist of BMP, Noggin, to determine whether a BMP antagonist blocks the action of vitamin D derivatives. As shown in Fig. 3B, the phosphorylation of Smad1/5 induced by the vitamin D₃ analog Ro3582 (10 nM) or BMP-2 (100 ng/ml) was inhibited by the antagonist Noggin (+, 60 ng/ml; ++, 300 ng/ml). In contrast, the induction of phospho-Smad3 (lower band) by TGF-β₁ (1 ng/ml) was not blocked by Noggin, whereas the
induction of pSmad1/5 (upper band) by Ro3582 was completely abolished by Noggin, confirming that induction of R-Smads by the vitamin D₃ analog Ro3582 is specific to BMP signaling.

**Vitamin D-Induced Increase in Phospho-Smad1/5 Is Not Due to the Inhibition of Phosphatase Activity.** As described above and in Fig. 4A, we observed an increased amount of phospho-Smad1/5 in MCF10AT1 cells treated with the vitamin D₃ analog. Because it was reported that vitamin D₃ analogs might regulate phosphatase activity (Bettoun et al., 2004), we determined whether the increased amount of phospho-Smad1/5 might be due to the inhibition of phosphatase activity in these cells. A serine/threonine phosphatase enzyme inhibitor, okadaic acid, is known to suppress the activity of protein phosphatases, mostly isotype PP2A, which accounts for most of the cellular activity. It has been shown that treatment of HL-60 leukemia cells with okadaic acid increased the level of phospho-Smad2 (Cao et al., 2003). In our study, okadaic acid did not significantly increase the phosphorylation of Smad2, Smad3, or Smad1/5 in MCF10AT1 cells, whereas the phosphorylation of Smad1/5 induced by the vitamin D₃ analog Ro3582 (10 nM) or BMP-2 (100 ng/ml) was shown (Fig. 4A). Second, we performed in vitro serine/threonine phosphatase enzyme assays to determine whether the vitamin D₃ analog Ro3582 inhibits phosphatase activity in MCF10AT1 cells. Using MCF10AT1 cell lysate as the source for the enzyme, Ro3582 (10, 100, and 1000 nM) or okadaic acid (OA, 10, 100, and 1000 nM) was added to the cell lysate and tested for its ability to inhibit phosphatase enzyme activity. Nonradioactive specific phosphopeptide RRA(pT)VA was used as a peptide substrate for serine/threonine protein phosphatases 2A, 2B, and 2C. Okadaic acid inhibited the phosphatase activity dose-dependently, whereas the vitamin D₃ analog Ro3582 did not inhibit the activity even at 1 µM (Fig. 4B).

**Nuclear Localization of Phospho-Smad1/5 Is Induced by Vitamin D₃ Analog Ro3582 in MCF10AT1 Breast Epithelial Cells.** Nuclear localization of activated Smad1/5 by the vitamin D₃ analog Ro3582 in MCF10AT1 breast epithelial cells is shown in Fig. 5. The phosphorylation of Smad1/5 and its localization in the nucleus is markedly increased by treatment with the vitamin D₃ analog Ro3582. As shown in Fig. 5, there is very low staining of phospho-Smad1/5 in the control (DMSO-treated) or Noggin control (300 ng/ml). However, when cells are treated with BMP-2 (100 ng/ml) or Ro3582 (1 nM), the phospho-Smad1/5 is mainly localized in the nucleus in the cells. Furthermore, when cells are treated with BMP-2 (100 ng/ml) or Ro3582 (1 nM) in the presence of the BMP antagonist Noggin, the accumulation of phospho-Smad1/5 in the nucleus induced by Ro3582 or BMP-2 was blocked. DAPI staining was used to recognize the nuclear morphology in cells.

**The Vitamin D₃ Analog Ro3582 Enhances BMP Transcriptional Activation in MCF10AT1 Breast Epithelial Cells.** Next, we determined whether increased phospho-Smad1/5 induced by the vitamin D₃ analog can lead to activation of BMP-mediated transcription using a transfection assay with a GC binding element linked to luciferase. This construct, 3GC2-Lux, contains three repeats of the GC-rich sequence derived from the proximal BMP response element in the Smad6 promoter (Ishida et al., 2000) and is specific for induction of luciferase by BMP.

![Fig. 4](image)

**Fig. 4.** Increased phospho-Smad1/5 is not due to the inhibition of phosphatase activity. A, MCF10AT1 cells (1 × 10⁶ cells/dish) were starved for 24 h in serum-free DMEM/Ham’s F-12 medium. Then cells were incubated with the indicated compounds in 0.1% BSA/DMEM/Ham’s F-12 medium for 24 h. The phosphorylation of Smad1/5 induced by the vitamin D₃ analog Ro3582 (10 nM) or BMP-2 (100 ng/ml) was shown, whereas TGF-β (1 ng/ml) or okadaic acid (10 and 100 nM) did not increase phospho-Smad1/5 in these cells. B, in vitro phosphatase assay was carried out using MCF10AT1 cell lysate. Ro3582 (10, 100, and 1000 nM) or okadaic acid (OA, 10, 100, and 1000 nM) was added to the cell lysate, and inhibition of phosphatase enzyme activity was determined using nonradioactive specific phosphopeptide RRA(pT)VA, a peptide substrate for serine/threonine protein phosphatases 2A, 2B, and 2C.

![Fig. 5](image)

**Fig. 5.** Nuclear localization of phospho-Smad1/5 induced by the vitamin D₃ analog Ro3582 in MCF10 breast epithelial cells. MCF10AT1 cells (30,000/chamber) were incubated with Ro3582 (1 nM) or BMP-2 (100 ng/ml) in the presence and absence of BMP antagonist, Noggin (300 ng/ml), in 0.1% BSA/DMEM/Ham’s F-12 medium for 24 h. The staining for phospho-Smad1/5 is shown as green, and DAPI staining for the nucleus is shown as blue. Immunofluorescence microscopy is shown (magnification, 63×).

![Fig. 6](image)

**Fig. 6.** The synthetic vitamin D₃ analog Ro3582 enhances BMP-dependent transcriptional activation. MCF10AT1 cells (40,000/well in 24-well plates) were plated and transfected with 3GC2-Lux vector (100 ng/well) for 6 h and further treated with Ro3582 at concentrations of 1, 0.1, and 0.01 nM for 24 h. Luciferase values were normalized for β-galactosidase activity.
response to BMPs. Human breast MCF10AT1 cells were transiently transfected with 3GC2-Lux vector and pCMV-β-gal. In the experiments shown in Fig. 6, cells were then treated with either DMSO or the vitamin D₃ analog Ro3582 (1, 0.1, or 0.01 nM) and incubated for 24 h before assaying for luciferase activity. When the BMP-dependent response to Ro3582 was determined using 3GC2-Lux vector, the vitamin D₃ analog increased this activity by 3-fold at 1 nM.

Fig. 7. The vitamin D₃ analog Ro3582 induces the mRNA and protein synthesis of BMP-2 and BMP-6 and inhibits the mRNA expression of Smad6.

A, MCF10AT1 cells (1 × 10⁶ cells/100-mm dish) were incubated with the vitamin D₃ analog Ro3582 (1 nM) in DMEM/Ham’s F-12 medium supplemented with 5% horse serum for 4 or 12 h. Total RNA was isolated, and the measurement of BMP-2, BMP-6, and Smad6 mRNA was performed as described under Materials and Methods. GAPDH values were used to normalize the production of the mRNA. Two separate experiments were performed. B, MCF10AT1 cells (5 × 10⁵ cells/100-mm dish) were starved for 24 h in serum-free DMEM/Ham’s F-12 medium. Then, cells were incubated with Ro3582 (1 and 10 nM) in 0.1% BSA/DMEM/Ham’s F-12 medium for 48 h. The supernatant was collected and stored at −20°C until assayed. The BMP-2 and BMP-6 protein synthesized and secreted into the medium was measured by the immunoassay using a BMP-2 and BMP-6 standard. Representative data are shown from two similar experiments. C, MCF10AT1 cells (1 × 10⁶ cells/100-mm dish) were starved for 24 h in serum-free DMEM/Ham’s F-12 medium. Then cells were incubated with the vitamin D₃ analog Ro3582 (10 nM) with or without Noggin (300 ng/ml) in DMEM/Ham’s F-12 medium supplemented with 0.1% BSA for 12 or 24 h. Total RNA was isolated, and the measurement of BMP-2 and BMP-6 mRNA was performed as described under Materials and Methods. GAPDH values were used to normalize the production of the mRNA. Two separate experiments were performed (statistical significance: *, p < 0.05; **, p < 0.01).
The Vitamin D₃ Analog Ro3582 Not Only Induces the Synthesis of mRNA and Protein of BMP-2 and BMP-6 but Also Inhibits the Expression of Smad6 mRNA. In Fig. 7A, MCF10AT1 cells were treated with the vitamin D₃ analog Ro3582 (1 nM) for 4 or 12 h, total RNA was harvested, and BMP-2, BMP-6, and Smad6 mRNA production was measured by quantitative polymerase chain reaction. We found that the vitamin D₃ analog Ro3582 (1 nM) induced BMP-2 and BMP-6 mRNA up to 3- and 10-fold, respectively, at 12 h. Furthermore, it down-regulated mRNA for Smad6, an inhibitor of BMP-mediated R-Smads, compared with the DMSO control (Fig. 7A). We also determined that the vitamin D₃ analog Ro3582 induced the synthesis of BMP-2 and BMP-6 protein in MCF10AT1 cells, as shown by immunoassay for BMP-2 and BMP-6 (Fig. 7B). Approximately 130 and 360 pg of BMP-2 protein and 360 and 400 pg of BMP-6 protein were synthesized from MCF10AT1 cells treated with the vitamin D₃ analog Ro3582 at 1 and 10 nM for 48 h, respectively (Fig. 7B). We also determined whether the synthesis of BMP-2 and BMP-6 mRNA induced by Ro3582 may be blocked by Noggin. The induction of both BMP-2 mRNA and BMP-6 mRNA production was significantly reversed by Noggin at 24 h (Fig. 7C).

Discussion

BMPs are members of the TGF-β superfamily that have multiple functions in development, bone formation, and tissue remodeling (Reinholz et al., 2002; Miyazono et al., 2005). BMPs have been identified as multifunctional regulators of proliferation, differentiation, and apoptosis, and the role of the BMP/Smad pathway in cancer is now being discussed intensively (Villanueva et al., 1998; Ghosh-Choudhury et al., 2000; Reinholz et al., 2002; Miyazaki et al., 2004). In this report, we investigated the action of vitamin D derivatives on Smad signaling proteins, which are known to be important cytoplasmic mediators of signals from the TGF-β/activin/BMP receptor serine/threonine kinases. We showed that the synthetic vitamin D₃ analog Ro3582 activated the BMP-specific Smad signaling system in MCF10 breast epithelial cells. The vitamin D₃ analog increased phosphorylation of receptor-regulated Smad1/5 (Fig. 2), translocated phosphorylated Smad1/5 into the nucleus (Fig. 5), and enhanced Smad1/5-independent activation of BMP-mediated gene transcription (Fig. 6). We also found that the vitamin D derivative induced the synthesis of mRNA and protein of BMP-2 and BMP-6 and reduced the expression of Smad6 mRNA (Fig. 7). Furthermore, our results showed that Noggin reversed the phosphorylation of Smad1/5 induced by Ro3582 (Fig. 3) and inhibited the nuclear localization of phospho-Smad1/5 by the vitamin D₃ analog Ro3582 (Fig. 5). In addition, the induction of BMP-2 and BMP-6 mRNA synthesis was blocked by Noggin (Fig. 7C). This is the first report demonstrating the activation of Smad1/5 by vitamin D₃ analogs and cross-talk between BMP and vitamin D signaling pathways in breast epithelial cells.

Interactions between the nuclear receptor family and TGF-β superfamily have been investigated for many years, and multiple levels of interactions between steroid receptors and the TGF-β superfamily have been identified. Steroids, such as vitamin D₃ analogs and retinoids, are known to enhance the response to TGF-β/BMP by inducing the synthesis of more TGF-β/BMP ligands and their receptors (Falk et al., 1991; Koli and Keski-Oja, 1995; Hatakeyama et al., 1996; Hallahan et al., 2003). Furthermore, there is now an abundant literature on the interaction of steroids and their nuclear receptors with Smads (Yanagi et al., 1999; Yanagisawa et al., 1999; Matsuda et al., 2001). In a study reported previously (Cao et al., 2003), it was shown that certain vitamin D₃ analogs induced phospho-Smad2 in myeloid leukemia cells and that phosphorylation of Smad2 is a critical sensor for the differentiation of these cells. In MCF10 breast epithelial cells, we have shown that vitamin D₃ analogs activated the BMP/Smad system by selectively phosphorylating Smad1/5 and increasing its nuclear localization.

Because it has been shown that C-terminal phosphorylation of R-Smads by the TGF-β type I receptor is a key event in the activation of Smads (Derynck and Zhang, 2003), we have used the antibody against Ser433/435 phosphorylation at the C-terminal domain of Smad3 and the antibody to pSmad1(Ser463/465)/pSmad5(Ser463/465)/pSmad8(Ser426/428) to determine the effects of the vitamin D₃ analogs on the TGF-β/BMP signaling system in MCF10 epithelial cells. Using these antibodies to the phospho-Smads, we found that the vitamin D₃ analog Ro3582 increased the phosphorylation of R-Smads responsible for activating the BMP pathway, namely Smad1/5, but not R-Smads of the TGF-β/activin pathways, Smad2 and Smad3. In the present study, we showed that activation of R-Smads by a vitamin D derivative was specific to BMP signaling, because its response was abrogated by the BMP antagonist Noggin. The selectivity of vitamin D₃ analogs to increase the phosphorylation of Smad1/5 but not Smad3 or Smad2 in MCF10 breast epithelial cells is of considerable interest, but further research is needed to determine the mechanism of this selectivity.

The vitamin D₃ analogs clearly increased the phosphorylation of Smad1/5 and further induced the translocation of Smad1/5 into the nucleus. It is known that R-Smads, such as Smad3 or Smad5, do not require Smad4 for nuclear translocation, although Smad4 can cotranslocate with the R-Smads. In our study, we found that Smad4 also translocated into the nucleus when the nuclear localization of phospho-Smad1/5 was induced by vitamin D₃ analogs (data not shown). Although treatment of the cells with TGF-β, BMP-2, or BMP-6 induces the phosphorylation of R-Smads within 30 min and the activation goes down gradually by 24 h, the vitamin D₃ analog Ro3582 did not induce the phosphorylation of Smad1/5 at 30 min (data not shown). A time course study indicated that the vitamin D₃ analog started to increase Smad1/5 phosphorylation at 12 h and increased the level of phosphorylation markedly by 24 h. These results indicate that activation of Smad1/5 by the vitamin D₃ analogs may not be caused by a direct action on Smad1/5 molecules, but it requires time for the activation or synthesis of the kinase that phosphorylates Smad1/5.

The possible mechanism of activation of Smad1/5 is that the vitamin D derivative functions by inhibiting phosphatases that dephosphorylate phospho-Smad1/5. However, this is not the case for the action of the vitamin D derivative in these MCF10 breast epithelial cells, as shown in Fig. 4. It is more likely that vitamin D analogs activate BMP-specific signaling by increasing the production of BMPs or by down-regulating the inhibitory system of the signaling such as Smad6. The results in Fig. 7 show that Ro3582 not only...
increased mRNA expression and protein synthesis of BMP-2 and BMP-6 but also reduced the Smad6 mRNA level. We also determined the expression level of BMP-7, but the basal level was too low to be detected by quantitative real time reverse transcription-polymerase chain reaction in MCF10AT1 cells (data not shown). These results support the hypothesis that vitamin D3 analogs activate BMP-specific signaling by increasing the synthesis of BMP-2 and BMP-6, but not BMP-7, as well as by down-regulating Smad6. Smad6 was identified as an inhibitory Smad by inhibiting the BMP/Smad signaling. It binds to BMP receptor type I and blocks the phosphorylation of Smad1/5 (Imamura et al., 1997; Chen et al., 2004), and it also inhibits the complex formation of Smad1 and Smad4 by binding to activated Smad1 (Hata et al., 1998). The activity of Smad ubiquitin regulator factor 1 is also enhanced through interacting with Smad6 (Murakami et al., 2003).

A potential role for the BMP/Smad pathway during the progression of estrogen receptor-positive breast cancer has been reported recently (Helms et al., 2005). However, the antiproliferative and proapoptotic effects of BMPs are reported in breast cancer cell lines, and significantly decreased expression of BMP-2 has been shown in noninvasive, invasive, and liver metastatic breast tumor tissue compared with normal breast tissue (Reinholz et al., 2002), suggesting a possible role of the BMP-2 as a tumor suppressor. Because we have shown that the vitamin D system interacts with BMP signaling, it will be interesting to determine whether vitamin D3 analogs induce growth suppression in breast cancer by the activation of BMP signaling and eventually can be used as potent chemopreventive agents in breast cancer.

In conclusion, the present study provides the first demonstration of the effects of 1α,25(OH)2D3 and vitamin D derivatives to enhance BMP/Smad signaling in breast epithelial cells. This effect occurs by inducing the phosphorylation of Smad1/5 in the cytoplasm followed by its translocation to the nucleus, where it may interact with the VDR or other molecules for transcription. Because breast cancer mainly metastasizes to the bone, in which BMPs play an important role in bone formation and bone metastasis, the enhancement of BMP signaling by vitamin D derivatives may be an important aspect of their antiproliferative, differentiating, apoptotic, or antimetastatic effects. An understanding of the functional significance of enhanced BMP signaling will require further investigation and may depend on the cell type and whether it is at an early or late stage of carcinogenesis.

Acknowledgments

We thank Drs. Allan Conney and Lalage Wakefield for helpful advice on our work. The MCF10 cell lines were established and provided by Dr. Fred Miller and his group at the Karmanos Cancer Institute. We thank Drs. Renping Zhou and Fang Liu and the Department of Chemical Biology for technical help with this project.
