ABSTRACT

Tolbutamide and gliclazide block the K$_{ATP}$ channel $K_{i,6.2}$/Sur1, causing membrane depolarization and stimulating insulin secretion in pancreatic beta cells. We examined the ability of the EPAC-selective cAMP analog 8-pCPT-2'-O-Me-cAMP-AM to potentiate the action of these drugs and the mechanism that might account for it. Insulin secretion stimulated by both 200 μM tolbutamide and 20 μM gliclazide, concentrations that had equivalent effects on membrane potential, was inhibited by thapsigargin (1 μM) or the L-type Ca$^{2+}$ channel blocker nicardipine (2 μM) and was potentiated by 8-pCPT-2'-O-Me-cAMP-AM at concentrations ≥2 μM in INS-1 cells. Ca$^{2+}$ transients stimulated by either tolbutamide or gliclazide were inhibited by thapsigargin or nicardipine and were significantly potentiated by 8-pCPT-2'-O-Me-cAMP-AM at 5 μM but not 1 μM. Both tolbutamide and gliclazide stimulated phospholipase C activity; however, only gliclazide did so independently of its activity at K$_{ATP}$ channels, and this activity was partially inhibited by pertussis toxin. 8-pCPT-2'-O-Me-cAMP-AM alone (5 μM) did not stimulate insulin secretion, but did increase intracellular Ca$^{2+}$ concentration significantly, and this activity was inhibited by 25 μM 2-aminoethoxydiphenylborate (2-APB) or the removal of extracellular Ca$^{2+}$. 8-pCPT-2'-O-Me-cAMP-AM potentiation of insulin secretion stimulated by tolbutamide was markedly inhibited by 2-APB (25 μM) and enhanced by the PKC inhibitor bisindolylmaleimide I (1 μM). Our data demonstrate that the actions of both tolbutamide and gliclazide are strongly potentiated by 8-pCPT-2'-O-Me-cAMP-AM, that gliclazide can stimulate phospholipase C activity via a partially pertussis toxin-sensitive mechanism, and that 8-pCPT-2'-O-Me-cAMP-AM potentiation of tolbutamide action may involve activation of a 2-APB-sensitive Ca$^{2+}$ influx.

Introduction

Sulfonylurea drugs, such as tolbutamide and gliclazide, have been used for decades to stimulate insulin secretion and decrease blood glucose levels in type 2 patients with diabetes with insufficient endogenous insulin secretion (Groop, 1992). These drugs bypass the metabolic steps required for glucose-stimulated insulin secretion and mimic the effect of an increase in ATP/ADP ratio (Rorsman and Trube, 1985; Dunne and Petersen, 1986) on the K$_{ATP}$ channel composed of the Kir6.2 and SUR1 subunits (Babenko et al., 1998). Binding of sulfonylureas to the K$_{ATP}$ channel favors channel closing (Schmid-Antomarchi et al., 1987) and subsequent membrane depolarization because open K$_{ATP}$ channels permit the efflux of K$^+$ ions and the maintenance of the membrane potential close to the equilibrium potential for K$^+$ (Cook and Hales, 1984). Depolarization of the membrane potential of pancreatic beta cells leads to the activation of several varieties of voltage-gated Ca$^{2+}$ channels (Horvath et al., 1998), including the L-type channels Ca$_{L}$,1.2 and Ca$_{L}$,1.3 (Seino et al., 1992). The subsequent rise in intracellular Ca$^{2+}$ triggers the exocytosis of insulin (Wollheim et al., 1975) via dense core vesicles that are shuttled to (Van Obberghen et al., 1975), and eventually fuse with, the plasma membrane (Barg et al., 2001; Shibasaki et al., 2007).

ABBREVIATIONS: 2-APB, 2-aminoethoxydiphenylborate; BIS, bisindolylmaleimide I; Carbachol-2, (trimethylazaniumyl)ethyl carbamate chloride; diazoxide, 7-chloro-3-methyl-4H-1,2,4-benzothiadiazine-1,1-dione; EPAC, exchange protein directly activated by cAMP; ESCA, EPAC-selective cAMP analog; gliclazide, 1-[[4-(methylbenzenesulfonyl)-3-{octahydrocyclopenta[c]pyrrol-2-yl}j]urea; IP$_3$, inositol monophosphate; nicardipine, 3-[benzyl(methyl)amino]ethyl]-5-methyl-2,6-dimethyl-4-(3-nitrophenyl)-1,4-dihydropyridine-3,5-dicarboxylate; 8-pCPT, 2'-O-Me-cAMP-AM-parachlorophenythio-2'-O-methyladenosine-3'-5'-cyclic monophosphate, acetoxymethyl ester; Rp-cAMPs, adenosine-3'-5'-cyclic monophosphorothioate, Rp-isomer; SERCA, sarco(endo)plasmic reticulum calcium ATPase; tolbutamide, 3-butylyl-1-[[4-(methylbenzenesulfonyl)]jurea; TRP, transient receptor potential; U73122, 1-[6-[[17β]-3-methoxyestra-1,3,5(10)-trien-17-yl]-amino]hexyl]-1H-pyrrole-2,5-dione; U73743, 1-[6-[[17β]-3-methoxyestra-1,3,5(10)-trien-17-yl]amino]hexyl]-2,5-pyrrolinedione.
Recently, exchange protein directly activated by cAMP 2 (EPAC2) was identified as a novel cellular target for some members of the sulfonylurea drug class (Zhang et al., 2009). EPAC2 is a guanine nucleotide exchange factor (GEF) for the low molecular weight GTP binding protein Rap1 (Kawasaki et al., 1998). In the cAMP-bound form, EPAC2 accelerates the exchange of GDP for GTP at the nucleotide binding site of Rap1 (Kawasaki et al., 1998). Along with the activation of protein kinase A (Ding and Gromada, 1997), activation of EPAC2 contributes to the potentiation of glucose-stimulated insulin secretion by incretin hormones that stimulate adenyl cyclase activity, such as GLP-1 (Lech et al., 2010a). The GTP-bound form of Rap1 is implicated in the activation of phospholipase C-β (Dzhura et al., 2010) in pancreatic beta cells, in augmenting the number of insulin granules in close proximity to sites of exocytosis on the plasma membrane (Shibasaki et al., 2007), and in the priming of insulin granules for exocytosis (Eliasson et al., 2003).

EPAC2 is thought to exist in a signaling complex with several other peripheral membrane proteins. EPAC2 interacts directly with SUR1 (Shibasaki et al., 2004) and with the C1Z protein piccolo (Fenster et al., 2000), which forms a dimer with the related protein RIM2 (Wang et al., 2000), in a Ca2+-dependent manner (Fujimoto et al., 2002). In addition, the voltage-gated Ca2+ channel Ca1.2 interacts with the C2 domains of RIM2 and piccolo via the intracellular II-III loop (Shibasaki et al., 2004). This signaling complex of scaffolding proteins (RIM2, piccolo), cAMP effector (EPAC2), and ion channel subunits (SUR1, Ca1.2) is of special significance because membrane depolarization-dependent calcium influx via Ca1.2 channels has been implicated in triggering Ca2+-induced Ca2+ release from the ER in pancreatic beta cells (Liu et al., 2006), a process that is amplified by cAMP, at least in part, through EPAC2 (Kang et al., 2003; Liu et al., 2006). The role of intrinsic EPAC2 stimulation by sulfonylureas on insulin secretion or the underlying Ca2+ dynamics in beta cells is currently unknown.

Tolbutamide and gliclazide, which both stimulate insulin secretion from pancreatic beta cells by block of KATP channels, differ in their ability to bind and activate EPAC2. Zhang et al. (2009), reported that tolbutamide at concentrations ≥30 μM significantly activated Rap1 in an EPAC2-dependent manner, whereas gliclazide at concentrations up to 30 nM did not. We used electrophysiological analysis to identify concentrations of tolbutamide and gliclazide that had equivalent effects on KATP channel activity both in terms of block of current and induction of membrane depolarization. We then used these concentrations of tolbutamide and gliclazide to compare stimulation of insulin secretion, stimulation of increases in intracellular Ca2+ concentration, and potentiation of these activities by the EPAC-selective cAMP analog (ESCA) 8-pCPT-2'-O-Me-cAMP-AM in INS-1 cells. Because activation of phospholipase C is a consequence of EPAC2 activation in pancreatic beta cells, we also assayed phospholipase C activation by tolbutamide and gliclazide in the absence and presence of diazoxide to prevent membrane depolarization and Ca2+ influx via voltage-gated Ca2+ channels. To gain insight into the mechanism whereby EPAC activation potentiates sulfonylurea action, we assayed 8-pCPT-2'-O-Me-cAMP-AM modulation of phospholipase C activity and intracellular Ca2+ concentration in INS-1 cells.

Materials and Methods

Chemicals. U73122 and U73343 were from Toeris (Minneapolis, MN); 8-pCPT-2'-O-Me-cAMP and 8-pCPT-2'-O-Me-cAMP-AM were from Biolog (Bremen, Germany). Rp-cAMP was from Santa Cruz Biotechnology (Santa Cruz, CA). Ryanodine was from Calbiochem (San Diego, CA). All other chemical reagents were obtained from Sigma-Aldrich (St. Louis, MO).

Cell Culture. INS-1 cells were grown in RPMI medium (Sigma-Aldrich) supplemented with 10% fetal bovine serum (HyClone, Logan, UT), 11 mg/ml sodium pyruvate, 10 mM HEPES, 100 U/ml penicillin, 100 μg/ml streptomycin, and 50 μM β-mercaptoethanol at 37°C, 5% CO2.

Electrophysiological Assay. Electrophysiological measurements in INS-1 cells were recorded at room temperature using an Axopatch 200B amplifier (Molecular Devices, Sunnyvale, CA) and fire-polished to resistances of 2–5 MΩ. For current-clamp experiments and voltage-clamp experiments to measure KATP channel current, the intracellular solution contained (in mM) 90 KSO4, 10 NaCl, 1 MgCl2, 1.1 EGTA, 0.1 CaCl2, 5 HEPES, 0.3 ATP, 0.2 GTP. The extracellular solution used for measuring KATP currents contained (in mM) 138 NaCl, 5.6 KCl, 11.1 glucose, 10 HEPES, 1.2 MgCl2, 2.6 CaCl2, and the NaCl was replaced with equimolar inositol 1,4,5-trisphosphate (InsP3) where indicated. The pH of both solutions was adjusted to 7.4 with NaOH, and the osmolality was adjusted to 290–300 mOsm. Whole cell KATP currents were elicited by 1.3-s steps of +20 mV from a holding potential of −70 mV. Data were acquired at a sampling frequency of 1 kHz. The membrane potential of INS-1 cells was measured using gap-free recording at a sampling frequency of 1 kHz in I = 0 current-clamp mode. The KATP channel opener, diazoxide (300 μM), was transiently applied to maximally open KATP channels, before application of tolbutamide or gliclazide. Tolbutamide and gliclazide solutions were prepared from stocks dissolved in 0.1 M NaOH made fresh daily. Diazoxide solutions were prepared from stocks dissolved in DMSO. For recordings of voltage-gated Ca2+ channel currents, the bath solution contained (in mM) 150 Tris, 10 BaCl2, 4 MgCl2. The intracellular solution contained (in mM) 130 N-methyl-D-glucamine, 10 EGTA, 60 HEPES, 2 ATP, and 1 MgCl2. The pH of both solutions was adjusted to 7.3 with methanesulfonic acid, and the osmolality was corrected to 290–300 mOsm. Current-voltage relationship data were collected by applying 100-mV test depolarizations from −50 to +60 mV in 10-mV increments from a holding potential of −70 mV. Data were acquired at a sampling frequency of 10 kHz and filtered at 1 kHz.

Insulin Secretion Assay. INS-1 cells were plated in 24-well tissue culture plate at 50–70% confluency and incubated overnight in RPMI medium supplemented as described above at 37°C, 5% CO2. Immediately before the assay, the cells were washed twice in phosphate-buffered saline [PBS: 137 mM NaCl, 10 mM phosphate, 2.7 mM KCl (pH 7.4)], and preincubated with a modified Kreb-Ringer buffer [KRBH: 134 mM NaCl, 3.5 mM KCl, 1.2 mM KH2PO4, 0.5 mM MgSO4, 1.5 mM CaCl2, 5 mM NaHCO3, 10 mM HEPES (pH 7.4)] supplemented with 0.05% fatty acid free BSA (KRHB buffer) alone or containing indicated concentrations of inhibitors for 30 min at 37°C, 5% CO2. The buffer was decanted and replaced with fresh KRHB buffer alone (basal condition) or KRHB containing the indicated concentrations of sulfonylurea with or without inhibitors for 1 hour at 37°C, 5% CO2. Secreted insulin was assayed using an ELISA for rat insulin (High-Range ELIA kit, ALPCO Diagnostics, Salem, NH). Cells were lysed in 20 mM Na2HPO4, 150 mM NaCl, 0.1% Triton X-100, 800 mM aprotinin, 50 μM leupeptin, 1 μg/ml pepstatin, 1 mM benzamidine, 1 mM 4-(2-aminophenyl)benzenesulfonfluoride, 10 μg/ml calpain inhibitor I, and 10 μg/ml calpain inhibitor II (pH 7.4), and cellular protein in each well was determined using the BCA assay (Thermo Scientific, Rockford, IL).

Intracellular Ca2+ Assays. INS-1 cells were plated at 100% confluency in black-walled 96 well plates (Corning Life Sciences,
Lowell, MA) in RPMI supplemented as described above, and incubated overnight at 37°C, 5% CO₂. Cells were washed twice with PBS and incubated with 5 μM Fura-2/acetoxymethyl ester (Fura-2 AM; Molecular Probes, Eugene, OR) diluted in KRBH for 1 hour at 37°C, 5% CO₂. The KRBH containing Fura-2 AM was then removed, and the cells were washed twice with KRBH and equilibrated for 30 min at 37°C, 5% CO₂ in the KRBH alone, or with indicated concentrations of inhibitors or 8-pCPT-2’-O-Me-cAMP-AM. When pertussis toxin was used, 25 ng/well was added to cells in 96-well plates approximately 18 hours before assay. Cells were stimulated by injection of the indicated concentration of sulfonlurea or 8-pCPT-2’-O-Me-cAMP-AM (or buffer control), and changes in intracellular Ca²⁺ concentrations were measured by recording the ratio of fluorescence intensities at 508/20 nm resulting from excitation of Fura-2 at 340/11 nm or 380/20 nm (center/band pass) using a Synergy 4 multi-mode microplate reader (BioTek, Winooski, VT). For experiments injecting sulfonlureas, ratios were acquired every 0.7 s for 15 s before injection and 2 minutes after injection of stimuli. For experiments injecting 8-pCPT-2’-O-Me-cAMP-AM, ratios were acquired every 5 s for 2 minutes before injection and at least 8 minutes after injection. Data were corrected for any injection artifact by subtracting the change in fluorescence ratio measured in cells injected with KRBH alone.

**IP₁ Assays.** INS-1 cells were plated at approximately 65,000 cells/well in white 96-well tissue culture plates (PerkinElmer, Waltham, MA) in the presence of 2.5 mM glucose overnight at 37°C and 5% CO₂. A prestimulation buffer was added to the cells for 1 hour before stimulation [10 mM HEPES, 1 mM CaCl₂, 0.5 mM MgCl₂, 4.2 mM KCl, 146 mM NaCl, 5 mM LiCl (pH 7.4)]. The prestimulation buffer was decanted, and treatments were made in a stimulation buffer containing LiCl to block inositol phosphate degradation [10 mM HEPES, 1 mM CaCl₂, 0.5 mM MgCl₂, 4.2 mM KCl, 146 mM NaCl, 5 mM LiCl (pH 7.4)]. Cells were incubated with treatments for 1 hour at 37°C, 5% CO₂. When pertussis toxin was used, 25 ng/well was added to cells in 96-well plates approximately 18 hours before assay. IP₁ levels were measured using the IP-One Tb Homogeneous Time-Resolved Fluorescence Resonance Energy Transfer (HTRF-FRET) Kit from Cisbio (Bedford, MA) according to the manufacturer’s instructions. The 620 nm/650 nm fluorescence ratio (excitation wavelength of 330 nM) was measured using a Synergy 4 fluorescent plate reader (BioTek). The concentration of IP₁ in each sample was determined by comparison of the 620 nm/650 nm ratio to those for a standard curve of IP₁ concentrations.

**Data Analysis.** Data were analyzed using SigmaPlot 11.0. Data are shown as means ± S.E. Statistical significance was determined using one-way analysis of variance and the Tukey’s post hoc test unless otherwise indicated. P < 0.05 was considered significant.

**Results**

**Electrophysiological Characterization of Tolbutamide and Gliclazide Activity in INS-1 Cells.** Both tolbutamide and gliclazide bind to and block the K<sub>ATP</sub> channel in pancreatic beta cells. To compare the effects of these two drugs and determine whether tolbutamide might also activate EPAC2 in INS-1 cells, we determined the potency of K<sub>ATP</sub> channel block and the dose response curve for membrane depolarization in INS-1 cells (Fig. 1). In the whole cell voltage-clamp mode, an alternating voltage-step protocol (stepping to −50 mV or −90 mV from a holding potential of −70 mV) elicited inward (at −90 mV) and outward (at −50 mV) K⁺ currents through K<sub>ATP</sub> channels (Fig 1A). These currents were blocked by increasing concentrations of either sulfonlurea drug, as indicated by the decrease in current amplitude in both directions. Plots of the percent of current block at each of several different concentrations of either tolbutamide or gliclazide yielded dose response curves that were fit as described in Materials and Methods. As expected, gliclazide was more potent in blocking of K<sub>ATP</sub> channel current than was tolbutamide (gliclazide IC<sub>50</sub> = 143 ± 23 nM; tolbutamide IC<sub>50</sub> = 2.6 ± 0.7 μM; Fig 1B).

Because the block of K<sub>ATP</sub> channels leads to membrane depolarization in pancreatic beta cells, we also measured the dose dependence for the membrane depolarization induced by tolbutamide or gliclazide. In current-clamp recordings using the zero-current injection mode, the resting membrane potential of INS-1 cells was found to be −75.1 ± 0.75 mV. Application of high concentrations of either tolbutamide (500 μM) or gliclazide (200 μM) caused similar, strong depolarization of the membrane potential that often led to firing of action potentials at voltages greater than −50 mV (Fig. 1C). Membrane potential repolarization occurred rapidly upon washout of tolbutamide. Washout of gliclazide was slower, but could be accelerated by application of 300 μM diazoxide, a K<sub>ATP</sub> channel “opener” (Fig. 1C). To compare the potency of tolbutamide and gliclazide in stimulating membrane potential depolarization, increasing concentrations of either drug were applied to INS-1 cells under current clamp. Tolbutamide and gliclazide both led to progressively greater depolarization of the membrane potential (Fig. 1D). Similar to block of K<sub>ATP</sub> channel current, gliclazide induced membrane depolarization more potently than did tolbutamide. The EC<sub>50</sub> for membrane depolarization by tolbutamide was determined to be 21.5 ± 10 μM with a maximum depolarization of 27.1 ± 4.2 mV. The EC<sub>50</sub> for membrane depolarization by gliclazide was determined to be 4.2 ± 0.9 μM with a maximum depolarization of 32.6 ± 3.8 mV. Because the concentrations of 20 μM gliclazide and 200 μM tolbutamide were maximally effective in their ability to induce membrane depolarization and were within error of each other, we used these concentrations for subsequent experiments to compare the ability of these sulfonlurea drugs to stimulate activities in INS-1 cells.

**Stimulation of Insulin Secretion and Ca²⁺ Transients by Tolbutamide and Gliclazide.** The concentrations of 20 μM gliclazide and 200 μM tolbutamide were used to induce insulin secretion in INS-1 cells using the static incubation method (Fig. 2). As expected from the electrophysiological characterization of the drugs, these concentrations of the sulfonlureas stimulated insulin secretion that was significantly different from basal secretion. Secretion stimulated by both 20 μM gliclazide and 200 μM tolbutamide was completely inhibited by 2 μM nicardipine, an L-type-selective Ca²⁺ channel blocker (Fig 2A). Nicardipine was used at 2 μM because we had shown previously that it completely inhibits L-type channels but does not substantially inhibit P/Q-type Ca²⁺ channels at this concentration (Lin et al., 2011). To assess the role of internal stores of Ca²⁺ in sulfonlurea-stimulated insulin secretion, the ability of 1 μM thapsigargin, an inhibitor of the sarcoplasmic/endoplasmic reticulum Ca²⁺-ATPase (SERCA), to inhibit insulin secretion stimulated by either gliclazide or tolbutamide was determined. We found that thapsigargin completely inhibited secretion stimulated by 20 μM gliclazide and significantly, but incompletely, blocked insulin secretion stimulated by 200 μM tolbutamide (Fig 2B). Thus, our results suggest that both influx of Ca²⁺ via L-type Ca²⁺ channels and release of internal stores of Ca²⁺ are required for maximal insulin secretion in response to gliclazide and tolbutamide stimulation.
Because sulfonylurea-stimulated insulin secretion was inhibited by nicardipine and thapsigargin, we examined the changes in intracellular Ca^{2+} concentration induced by tolbutamide or gliclazide. INS-1 cells in 96-well plates were loaded with the Ca^{2+} indicator Fura-2-AM, and changes in the ratio of fluorescence intensity at 510 nm after excitation at 340 nm and 380 nm (340 nm/380 nm ratio) were measured upon injection of tolbutamide (final concentration of 200 μM) or gliclazide (final concentration 20 μM). The changes in 340 nm/380 nm ratio upon sulfonylurea injection were corrected by subtracting the changes in 340 nm/380 nm ratio measured in replicate wells of INS-1 cells upon injection of buffer only. The net change in fura2 fluorescence ratio, reflecting the net change in intracellular Ca^{2+} concentration stimulated by tolbutamide and gliclazide.
tobutamide or gliclazide, is shown in Fig. 2. Both drugs induced a biphasic rise in intracellular Ca²⁺ concentration, with a rapid peak that decayed to an elevated plateau that persisted until the end of the 2-minute measurement (black circles: tobutamide, Fig. 2, C and E; gliclazide, Fig. 2, D and F). Pretreatment of INS-1 cells with 2 μM nicardipine for 30 minutes before injection of sulfonylureas completely inhibited this response. The portion of the response to each sulfonylurea that was sensitive to nicardipine (sulfonylurea response) is shown as white circles in Fig. 2C (tobutamide) and Fig. 2D (gliclazide). Pretreatment of INS-1 cells with 1 μM thapsigargin for 30 minutes before injection of sulfonylureas selectively inhibited the rapid peak in intracellular Ca²⁺ concentration, with minimal effect on the sustained plateau phase stimulated by either tobutamide or gliclazide. The portion of the response to each sulfonylurea that was sensitive to thapsigargin pretreatment is shown as white circles in Fig. 2E (tobutamide) and Fig. 2F (gliclazide). Thus, Ca²⁺ transients stimulated by either tobutamide or gliclazide are completely blocked by nicardipine, whereas thapsigargin selectively inhibits the early phase of the transient. The close correlation between block of insulin secretion and block of the early phase of the Ca²⁺ transient by nicardipine and thapsigargin supports that this rapid peak in intracellular Ca²⁺ concentration is particularly important in sulfonylurea-stimulated insulin secretion in INS-1 cells.

Potentiation of Sulfonylurea-Stimulated Insulin Secretion by 8-pCPT-2'-O-Me-cAMP-AM. Because tobutamide is reported to directly activate EPAC2 (Zhang et al., 2009), we next asked if the insulin secretion stimulated by 200 μM tobutamide or 20 μM gliclazide was differentially potentiated by the EPAC-selective cAMP analog 8-pCPT-2'-O-Me-cAMP-AM. As shown in Fig. 3A, insulin secretion was stimulated with 200 μM tobutamide or 20 μM gliclazide was differentially potentiated by the EPAC-selective cAMP analog 8-pCPT-2'-O-Me-cAMP-AM. Tolbutamide-stimulated insulin secretion was significantly potentiated by 8-pCPT-2'-O-Me-cAMP-AM at concentrations ≥2.0 μM. The potentiation of secretion over that stimulated by tobutamide alone was 1.47-fold and 1.92-fold at 2 μM and 5 μM 8-pCPT-2'-O-Me-cAMP-AM, respectively. When the same concentrations of 8-pCPT-2'-O-Me-cAMP-AM were used in combination with 20 μM gliclazide to stimulate insulin secretion (Fig. 3A), we found that significant potentiation of the response occurred at concentrations ≥2.0 μM as well. The potentiation of secretion over that stimulated by gliclazide alone was 1.47-fold and 2.1-fold at 2 μM and 5 μM 8-pCPT-2'-O-Me-cAMP-AM, respectively. Moreover, the insulin secretion stimulated by 200 μM tobutamide (199.3 ± 13 ng insulin/mg protein; n = 14)
and extent of potentiation of both 200 μM tolbutamide and 20 μM gliclazide-stimulated insulin secretion by 8-pCPT-2′-O-Me-cAMP-AM are essentially identical.

To ensure that the potentiation of insulin secretion by 8-pCPT-2′-O-Me-cAMP-AM that we observed with both tolbutamide and gliclazide was not mediated by cross-activation of protein kinase A (PKA), we tested the ability of the PKA-specific inhibitor Rp-adenosine-3′,5′-cyclic monophosphorothioate (Rp-cAMPs) to inhibit the potentiation of sulfonylurea-stimulated insulin secretion by 8-pCPT-2′-O-Me-cAMP-AM. As shown in Fig. 3B, 100 μM Rp-cAMPs did not significantly inhibit the potentiation of either tolbutamide- or gliclazide-stimulated insulin secretion by 5 μM 8-pCPT-2′-O-Me-cAMP-AM. However, 2 μM nicardipine completely blocked insulin secretion stimulated by tolbutamide or gliclazide in the presence of 5 μM 8-pCPT-2′-O-Me-cAMP-AM (Fig. 3C). Thus, 5 μM 8-pCPT-2′-O-Me-cAMP-AM potentiates insulin secretion stimulated by tolbutamide or gliclazide in a manner that does not involve PKA, but does require activation of L-type Ca2+-channels.

**Potentiation of Sulfonylurea-Stimulated Intracellular Ca2+ Transients by 8-pCPT-2′-O-Me-cAMP-AM.** Because 5 μM, but not 1 μM, 8-pCPT-2′-O-Me-cAMP-AM potentiated insulin secretion stimulated by either tolbutamide or gliclazide, we tested the ability of these concentrations of 8-pCPT-2′-O-Me-cAMP-AM to potentiate the Ca2+ transient stimulated by tolbutamide or gliclazide. Fura2-loaded INS-1 cells were pretreated with 0, 1, or 5 μM 8-pCPT-2′-O-Me-cAMP-AM for 30 minutes prior to injection of either buffer only, 200 μM tolbutamide, or 20 μM gliclazide. The net change in fura2 fluorescence ratio (sulfonylurea response – buffer only response) is shown for a representative experiment with tolbutamide (Fig. 4A) or gliclazide (Fig. 4B). Pretreatment with 5 μM 8-pCPT-2′-O-Me-cAMP-AM markedly and selectively increased the early peak of the Ca2+ transient stimulated by either sulfonylurea over pretreatment with buffer alone or 1 μM 8-pCPT-2′-O-Me-cAMP-AM. Area under the curve (AUC) analysis for the entire post-injection time course of three separate experiments revealed that pretreatment with 5 μM, but not 1 μM, 8-pCPT-2′-O-Me-cAMP-AM significantly increased the Ca2+-induced by tolbutamide or gliclazide compared with control cells (Fig. 4, C and D, respectively). Thus, just as observed for potentiation of sulfonylurea-stimulated insulin secretion, 5 μM, but not 1 μM, 8-pCPT-2′-O-Me-cAMP-AM significantly increased the magnitude of the Ca2+ transient in response to sulfonylurea stimulation, and the concentration threshold for potentiation of the tolbutamide response did not differ from that for gliclazide.

**Activation of Phospholipase C by Tolbutamide or Gliclazide in INS-1 Cells.** Because tolbutamide, but not gliclazide, is reported to directly activate EPAC2, we compared the ability of gliclazide and tolbutamide to stimulate phospholipase C activity in these cells. The concentrations of inositol-1-phosphate (IP1) in the presence of LiCl [to inhibit inositol-1-phosphate phosphatase (Hallcher and Sherman, 1980)] after stimulation with the muscarinic receptor agonist carbachol (500 μM) was measured in INS-1 cells using homogeneous time-resolved FRET (HTRF). Muscarinic acetylcholine receptor agonists, such as carbachol, stimulate phospholipase C activity in pancreatic beta cells (Yada et al., 1995) and INS-1 cells (Jacob et al., 2009). The phospholipase

---

**Fig. 3.** Potentiation of tolbutamide- or gliclazide-stimulated insulin secretion by the EPAC-selective cAMP analog (ESCA) 8-pCPT-2′-O-Me-cAMP-AM. (A) 200 μM tolbutamide and 20 μM gliclazide both stimulated insulin secretion that was significantly potentiated by 8-pCPT-2′-O-Me-cAMP-AM (ESCA) at concentrations ≥2 μM. ***P < 0.001; P < 0.05 compared with sulfonylurea and sulfonylurea + all concentrations of 8-pCPT-2′-O-Me-cAMP-AM; ***P < 0.001, *P < 0.05 compared with sulfonylurea alone (n = 9–14 in 3–5 independent experiments). (B) potentiation of tolbutamide- and gliclazide-stimulated insulin secretion by 8-pCPT-2′-O-Me-cAMP-AM is not blocked by the selective PKA inhibitor Rp-cAMPs (100 μM). ***P < 0.001 compared with sulfonylurea alone: sulfonylurea and ESCA +/- Rp-cAMPs were not significantly different (P = 0.089 for Tolb, P = 0.91 for Glz) (n = 9 in 3 independent experiments). (C) potentiation of tolbutamide- and gliclazide-stimulated insulin secretion by 5 μM 8-pCPT-2′-O-Me-cAMP-AM is completely blocked by the L-type Ca2+ channel blocker nicardipine (2 μM). ***P < 0.001; **P < 0.01, *P < 0.05 compared with basal (n = 9 in 3 independent experiments).
C inhibitor U73122 and its inactive analog U73343 were used to define specific phospholipase C activity stimulated by 500 μM carbachol, 200 μM tolbutamide, or 20 μM gliclazide in the HTRF assay for IP1. As shown in Fig. 5A, 500 μM carbachol stimulated IP1 accumulation in INS-1 cells that was completely blocked by either 100 μM atropine, a muscarinic receptor antagonist, or 10 μM U73122, but not 10 μM U73343. Stimulation of INS-1 cells with 200 μM tolbutamide or 20 μM gliclazide also resulted in a significant increase in IP1 accumulation over basal levels that was completely inhibited by 10 μM U73122, but not 10 μM U73343 (Fig. 5, B and C). Although U73122 and U73343 gave the expected results in our experiments measuring IP1 accumulation, we did not use these compounds in experiments measuring changes in intracellular Ca2+ concentration because we found that 10 μM U73122 irreversibly blocks ~80% and 10 μM U73343 reversibly blocks ~50% of the voltage-gated Ca2+ channel activity in INS-1 cells (Supplemental Fig. 1).

Because membrane depolarization is reported to stimulate phospholipase C activity in INS-1 cells (Thore et al., 2004), we further asked if carbachol, tolbutamide, or gliclazide could stimulate IP1 accumulation in the presence of the KATP channel opener diazoxide. As expected, 500 μM carbachol stimulated a significant increase in IP1 accumulation over basal levels that was completely blocked by 100 μM atropine in the presence or absence of 300 μM diazoxide (Fig. 5D). However, diazoxide incompletely, but significantly, reduced the IP1 accumulation stimulated by carbachol, suggesting that membrane depolarization contributes to carbachol activation of phospholipase C activity. In contrast, diazoxide completely inhibited the ability of 200 μM tolbutamide to stimulate IP1 accumulation above basal levels (Fig. 5E). Similar to what was observed with carbachol, 20 μM gliclazide significantly stimulated IP1 accumulation above basal levels in the presence or absence of diazoxide, although this increase was significantly greater in the absence of diazoxide (Fig. 5F).

To ensure that membrane potential depolarization was not contributing to the diazoxide-resistant IP1 accumulation observed with gliclazide, we measured the membrane potential in INS-1 cells stimulated with either 200 μM tolbutamide or 20 μM gliclazide and subsequently treated with 300 μM diazoxide in the continued presence of sulfonylurea drug. Figure 5G shows representative traces of whole cell current-clamp recordings of INS-1 cells depolarized with 200 μM tolbutamide (Fig. 5G, left) or 20 μM gliclazide (Fig. 5G, right). After the membrane depolarization induced by each drug had reached its maximum, 300 μM diazoxide was coapplied with the sulfonylureas. With both tolbutamide and gliclazide, the resting membrane potential was rapidly re-established when 300 μM diazoxide was present. Figure 5H summarizes the results of five or six separate experiments with 200 μM tolbutamide or 20 μM gliclazide and 300 μM diazoxide and shows that the membrane potential in the presence of diazoxide and tolbutamide or gliclazide is not different from the resting membrane potential before application of either sulfonylurea drug. Taken together, our results show that gliclazide, but not tolbutamide, is capable of stimulating phospholipase C activity independently of its KATP channel-blocking activity.

Evidence That Gliclazide Stimulates a Go coupled Receptor. One possibility that might explain the KATP channel-independent activity of gliclazide is that it activates a G protein-coupled receptor that can stimulate phospholipase C activity. Therefore, we asked whether pertussis toxin, an inhibitor of Go protein function, could interfere with the gliclazide stimulation of phospholipase C activity in the presence of diazoxide. Figure 6A shows that pretreatment of INS-1 cells in 96-well plates with 25 ng/well of pertussis toxin for 18 hours at 37°C, 5% CO2 significantly, but incompletely, inhibited the ability of 20 μM gliclazide to stimulate IP1 accumulation in the presence of 300 μM diazoxide. Increasing the amount of pertussis toxin used in the pretreatment to 50 ng/well did not further increase the extent of inhibition (data not shown). In contrast, pertussis toxin pretreatment had no effect on basal IP1 levels in the presence of 300 μM diazoxide (Fig. 6A). If gliclazide is, in fact, able to stimulate phospholipase C activity in the absence of membrane depolarization via activation of a Go coupled receptor, then gliclazide should also stimulate a Ca2+
transient in the presence of diazoxide. Figure 6B is a representative experiment showing 20 μM gliclazide stimulation of Ca\(^{2+}\) transients in fura2-loaded INS-1 cells in the absence or presence of 300 μM diazoxide. A rise in intracellular Ca\(^{2+}\) concentration in the presence of diazoxide was clearly detectable. The magnitude of the response (area under the curve) to gliclazide in the presence of diazoxide was significantly greater than that stimulated by 200 μM tolbutamide under the same conditions (Fig. 6B, inset).

We next examined the ability of ryanodine to block Ca\(^{2+}\) transients stimulated by tolbutamide or gliclazide. We reasoned that Ca\(^{2+}\) transients stimulated by Ca\(^{2+}\)-induced Ca\(^{2+}\) release would be sensitive to ryanodine, but Ca\(^{2+}\) release stimulated by activation of phospholipase C via IP\(_3\) receptors would not. We found that pretreatment of INS-1 cells with 20 μM ryanodine for 30 minutes before injection of sulfonylureas completely inhibited the early phase of the rise in intracellular Ca\(^{2+}\) in response to 200 μM tolbutamide (Fig. 6C; ryanodine-sensitive: white circles). However, pretreatment of INS-1 cells with 20 μM ryanodine did not strongly inhibit the Ca\(^{2+}\) transient stimulated by 20 μM gliclazide (Fig. 6D; ryanodine-sensitive: white circles). We next tested the requirement for physiologic concentrations of extracellular Ca\(^{2+}\) in the ryanodine-resistant transients stimulated by gliclazide. Figure 6E shows that in KRBH with zero added Ca\(^{2+}\), 20 μM gliclazide was still able to stimulate a robust increase in intracellular Ca\(^{2+}\) concentration in the presence or absence of 20 μM ryanodine. To examine a possible role of G\(_{i/o}\)-coupled receptors in this gliclazide-stimulated, ryanodine-insensitive Ca\(^{2+}\) transient, we pretreated INS-1 cells in 96-well plates with 25 ng/well of pertussis toxin (PTx) for 18 hours at 37°C, 5% CO\(_2\) and measured the Ca\(^{2+}\) transients stimulated by...
20μM gliclazide in the presence of 20μM ryanodine. A representative of six independent experiments is shown in Fig. 6F. Area under the curve analysis of these six experiments, normalized to the gliclazide response, revealed that PTx pretreatment did not significantly reduce the ability of gliclazide to stimulate a rise in intracellular Ca\(^{2+}\) concentration in the presence of ryanodine. Together, the data in Fig. 6 suggest that gliclazide stimulates phospholipase C activity independently of K\(_{ATP}\) channel block and that this activity is, in part, mediated by a G\(_i/o\)-dependent mechanism. This unique activity of gliclazide is correlated with stimulation of a more robust Ca\(^{2+}\) transient independently of activation of ryanodine receptors does not involve a G\(_i/o\)-dependent mechanism and does not require influx of Ca\(^{2+}\) across the plasma membrane.

8-pCPT-2′-O-Me-cAMP Does Not Enhance Membrane Depolarization Stimulated by 200μM Tolbutamide or 20μM Gliclazide or Voltage-Gated Ca\(^{2+}\) Channel Activity in INS-1 Cells. To further elicit the mechanism of 8-pCPT-2′-O-Me-cAMP potentiation of insulin secretion stimulated by tolbutamide or gliclazide in INS-1 cells, we used whole cell current-clamp measurements of membrane potential depolarization induced by these sulfonylureas in the presence or absence of 8-pCPT-2′-O-Me-cAMP. In these experiments 5μM 8-pCPT-2′-O-Me-cAMP, not the acetoxymethyl ester, was included in the pipette solution and allowed to dialyze into the cells for 10 min before either 200μM tolbutamide or 20μM gliclazide was applied via bath perfusion. We found that addition of 5μM 8-pCPT-2′-O-Me-cAMP to the pipette solution did not significantly alter the extent of membrane potential depolarization induced by either sulfonylurea (Fig. 7A). The effect of 5μM 8-pCPT-2′-O-Me-cAMP dialysis into the cells on whole cell voltage-gated Ca\(^{2+}\) channel currents was also assessed. Addition of 5μM 8-pCPT-2′-O-Me-cAMP to the pipette solution did not change the Ba\(^{2+}\) current density or the voltages at which whole cell
voltage-dependent $\text{Ba}^{2+}$ currents activated, from a holding potential of $-70 \text{ mV}$, at either 3 min or >10 min after break-in compared with control cells (Fig. 7, B and C). However, an approximately $-15 \text{ mV}$ shift in the reversal potential of voltage-dependent $\text{Ba}^{2+}$ current was observed after 10 minutes with 5 $\mu$M 8-pCPT-2’-O-Me-cAMP in the pipette (Fig. 7C). This shift in reversal potential was likely due to an increase in membrane permeability to the organic cation N-methyl-D-glucamine (NMDG) present in the intracellular solution, because it was abolished by equalizing the NMDG concentration in the intracellular and extracellular solutions (Fig. 7C). In contrast, no shift was observed in controls cells in which 0.1% DMSO (vehicle for 8-pCPT-2’-O-Me-cAMP) was included in the intracellular solution. The kinetics of current activation and inactivation were also unaffected by 5 $\mu$M 8-pCPT-2’-O-Me-cAMP as illustrated in Fig. 7D, which shows $\text{Ba}^{2+}$ current measured at 0 $\text{ mV}$ from a holding potential of $-70 \text{ mV}$, in a single cell, at break-in and 10 minutes after break-in. Thus, at a concentration that significantly potentiated insulin secretion, 8-pCPT-2’-O-Me-cAMP had no detectable effect on membrane potential depolarization induced by either 200 $\mu$M tolbutamide or 20 $\mu$M gliclazide or on the amplitude and voltage dependence of voltage-gated $\text{Ca}^{2+}$ channel activity in INS-1 cells. However, 5 $\mu$M 8-pCPT-2’-O-Me-cAMP, applied via the patch pipette, did enhance membrane permeability to the organic cation NMDG.

### Activation of Phospholipase C Activity by 8-pCPT-2’-O-Me-cAMP-AM

Because activation of EPAC2 leads to activation of PLC-$\varepsilon$ via Rap1 (Dzhura et al., 2010), we examined the ability of the concentrations of 8-pCPT-2’-O-Me-cAMP-AM that gave significant potentiation of insulin secretion by tolbutamide or gliclazide to stimulate an increase in cellular phospholipase C activity. As expected, 500 $\mu$M carbachol stimulated an increase in IP$_1$ accumulation in INS-1 cells that was completely blocked by 100 $\mu$M atropine (Fig. 8A). Concentrations of 8-pCPT-2’-O-Me-cAMP-AM from 1-20 $\mu$M did not stimulate IP$_1$ accumulation above the basal level. However, 50 $\mu$M 8-pCPT-2’-O-Me-cAMP-AM applied to INS-1 cells significantly increased IP$_1$ accumulation to an extent that was not different from that stimulated by 500 $\mu$M carbachol (Fig. 8A). Because 5 $\mu$M 8-pCPT-2’-O-Me-cAMP-AM was sufficient to strongly potentiate both insulin secretion and $\text{Ca}^{2+}$ transients stimulated by tolbutamide or gliclazide, we looked for other evidence that 5 $\mu$M 8-pCPT-2’-O-Me-cAMP-AM could, in fact, stimulate phospholipase C activity. If the HTRF assay for IP$_1$ is not sensitive enough to detect very low concentrations of IP$_1$ generated by 5 $\mu$M 8-pCPT-2’-O-Me-cAMP-AM, we reasoned that a small rise in...
in intracellular Ca\textsuperscript{2+} stimulated by low levels of phospholipase C activation might be detectable. Therefore, we applied increasing concentrations of 8-pCPT-2'-O-Me-cAMP-AM to fura2-loaded INS-1 cells and measured the change in 340 nm/380 nm ratio over 8-10 minutes. This longer time scale was used because 8-pCPT-2'-O-Me-cAMP-AM must be desalted intracellularly before it becomes active. We found that 8-pCPT-2'-O-Me-cAMP-AM dose dependently increased intracellular Ca\textsuperscript{2+} concentrations and that a significant increase over basal was observed at concentrations as low as 2 \mu M and 5 \mu M (Fig. 8B). The rise in intracellular Ca\textsuperscript{2+} stimulated by 5 \mu M 8-pCPT-2'-O-Me-cAMP-AM was significantly blocked by preincubation of cells with 25 \mu M 2-aminoethoxydiphenylborate (2-APB) (Fig. 8C). Because 2-APB is able to block both IP\textsubscript{3} receptors and TRP channels (Bootman et al., 2002), we examined the ability of 5 \mu M 8-pCPT-2'-O-Me-cAMP-AM to stimulate Ca\textsuperscript{2+} transients in the absence of extracellular Ca\textsuperscript{2+}. We found that 5 \mu M 8-pCPT-2'-O-Me-cAMP-AM stimulation of Ca\textsuperscript{2+} transients in INS-1 cells was abolished by removal of Ca\textsuperscript{2+} from the extracellular solution (Fig. 8C). Thus, even though we were unable to detect an increase in IP\textsubscript{1} levels stimulated by 5 \mu M 8-pCPT-2'-O-Me-cAMP-AM, it does stimulate a small, but detectable, increase in intracellular Ca\textsuperscript{2+} that could mediate the potentiation of sulfonylurea action.

Because 2-APB inhibits the 8-pCPT-2'-O-Me-cAMP-AM-stimulated increase in intracellular Ca\textsuperscript{2+} concentration, we tested the ability of 2-APB to inhibit 8-pCPT-2'-O-Me-cAMP-AM potentiation of tolbutamide-stimulated insulin secretion. We chose tolbutamide over gliclazide for these experiments to avoid the K\textsubscript{ATP} channel-independent activity of gliclazide. As shown in Fig. 8D, 5 \mu M 8-pCPT-2'-O-Me-cAMP-AM increased insulin secretion stimulated by 200 \mu M tolbutamide by approximately twofold, whereas addition of 25 \mu M 2-APB alone did not significantly affect tolbutamide-stimulated insulin secretion. However, when INS-1 cells were treated with 25 \mu M 2-APB + 5 \mu M 8-pCPT-2'-O-Me-cAMP-AM, tolbutamide-stimulated insulin secretion was not different from that measured in the absence of either compound. Thus, 25 \mu M 2-APB significantly blocked both the increase in intracellular Ca\textsuperscript{2+} concentration and the potentiation of tolbutamide-stimulated insulin secretion stimulated by 5 \mu M 8-pCPT-2'-O-Me-cAMP-AM in INS-1 cells.
Modulation of 8-pCPT-2′-O-Me-cAMP-AM Potentiation of Tolbutamide Action by Bisindolylmaleimide I. Protein kinase C (PKC) is a potential downstream effector of the small increase in intracellular Ca\textsuperscript{2+} stimulated by low concentrations of 8-pCPT-2′-O-Me-cAMP-AM. PKC is activated by Ca\textsuperscript{2+} and is reported to phosphorylate RYR2 and enhance Ca\textsuperscript{2+}-induced Ca\textsuperscript{2+} release in cardiac muscle downstream of EPAC activation (Oestreich et al., 2009). We therefore examined the ability of the broad-spectrum PKC inhibitor bisindolylmaleimide I (BIS) to inhibit potentiation of tolbutamide action by 8-pCPT-2′-O-Me-cAMP-AM (Fig. 9). As shown in Fig. 9A, preincubation with 1 μM BIS significantly increased the amplitude of the Ca\textsuperscript{2+} transient stimulated by 200 μM tolbutamide to a similar extent as 5 μM 8-pCPT-2′-O-Me-cAMP-AM. The combination of BIS and 8-pCPT-2′-O-Me-cAMP-AM also significantly increased the amplitude of the Ca\textsuperscript{2+} transient stimulated by tolbutamide, but there was no further increase over that observed with BIS or 8-pCPT-2′-O-Me-cAMP-AM alone. We next examined the ability of BIS to potentiate insulin secretion stimulated by tolbutamide. Consistent with the modulation of Ca\textsuperscript{2+} transients, 1 μM BIS also potentiated the insulin secretion stimulated by 200 μM tolbutamide (Fig. 9C). In contrast to the experiments measuring Ca\textsuperscript{2+} transients, the combination of 1 μM BIS + 5 μM 8-pCPT-2′-O-Me-cAMP-AM potentiated insulin secretion stimulated by tolbutamide to a greater extent than 1 μM BIS alone (Fig. 9D). Because inhibition of PKC potentiates both tolbutamide-stimulated Ca\textsuperscript{2+} transients and insulin secretion, it is unlikely that activation of PKC by EPAC2/Rap1 stimulation of phospholipase C activity plays a role in the potentiation of sulfonylurea-stimulated Ca\textsuperscript{2+} transients or insulin secretion.

Discussion

Potentiation of Tolbutamide- or Gliclazide-stimulated Insulin Secretion and Ca\textsuperscript{2+} Transients by the EPAC-selective cAMP Analog 8-pCPT-2′-O-Me-cAMP Is Not Different in INS-1 Cells. Previous studies reported that the sulfonylurea tolbutamide is able to directly activate EPAC2 while the structurally distinct sulfonylurea gliclazide is not (Zhang et al., 2009). We tested this conclusion in the rat pancreatic β-cell line INS-1 using a pharmacological approach. If tolbutamide activates EPAC2 in INS-1 cells, we...
would expect that tolbutamide might stimulate insulin secretion to a greater extent than gliclazide at concentrations of the drugs that are equivalent in terms of their activity at the K<sub>ATP</sub> channels. In fact, we found that at such concentrations, tolbutamide and gliclazide stimulated insulin secretion to the same extent (Fig. 3A). In addition, if tolbutamide was able to activate EPAC2 directly in INS-1 cells, we would expect that gliclazide-stimulated secretion would be more sensitive to potentiation by 8-pCPT-2′-O-Me-cAMP-AM. However, we found that the concentration at which 8-pCPT-2′-O-Me-cAMP-AM potentiation of insulin secretion reached significance was identical for both sulfonylureas (i.e., 2 μM; Fig. 3A). In addition, the Ca<sup>2+</sup> transient stimulated by either sulfonylurea was significantly potentiated by 8-pCPT-2′-O-Me-cAMP-AM at 5 μM, but not at 1 μM (Fig. 4). These findings are inconsistent with a direct activation of EPAC2 by 200 μM tolbutamide, but not 20 μM gliclazide, in INS-1 cells.

8-pCPT-2′-O-Me-cAMP Potentiation of Sulfonylurea-Stimulated Insulin Secretion and Ca<sup>2+</sup> Transients Does Not Require Activation of PKA or Enhancement of Membrane Depolarization. The mechanism by which 8-pCPT-2′-O-Me-cAMP-AM potentiates insulin secretion by sulfonylureas was also examined. The concentrations of 8-pCPT-2′-O-Me-cAMP-AM used in this study are very likely to be selective for activation of EPAC over PKA because even 1 mM 8-pCPT-2′-O-Me-cAMP-AM activated <25% of PKA activity at physiologic concentrations of the enzyme (Christensen et al., 2003). However, sulfonylurea stimulation of pancreatic β-cells has been reported to stimulate adenylyl cyclase activity (Grill and Cerasi, 1978). Therefore, endogenously produced cAMP, and activation of PKA, could potentially contribute to the activities of tolbutamide and gliclazide observed in this study. To test this possibility, we asked if the PKA-selective inhibitor Rp-cAMPs could interfere with 8-pCPT-2′-O-Me-cAMP-AM potentiation of sulfonylurea-stimulated insulin secretion; however, a role for PKA activity was excluded because 100 μM Rp-cAMPs had no effect (Fig. 3). This result contrasts with a previous report that potentiation of glucose-stimulated insulin secretion by 8-pCPT-2′-O-Me-cAMP-AM was markedly attenuated by inhibitors of PKA in human islets (Chepurny et al., 2010). This discrepancy may result from differences between glucose stimulation of β-cells, which generates many glucose metabolites, and sulfonylurea stimulation, which more specifically regulates membrane potential.

A previous study (Leech et al., 2010b) found that 8-pCPT-2′-O-Me-cAMP-AM at concentrations of 10 μM and 50 μM increased the sensitivity of K<sub>ATP</sub> channels in excised membrane patches to relatively low concentrations of tolbutamide. However, as channel block by tolbutamide approached saturation, this effect of 8-pCPT-2′-O-Me-cAMP-AM became insignificant. Our analysis of the electrophysiological effects of 5 μM 8-pCPT-2′-O-Me-cAMP-AM on INS-1 cells did not reveal any potentiation of sulfonylurea-induced membrane depolarization or any enhancement of voltage-gated Ca<sup>2+</sup> channel activity (Fig. 7). This is not surprising given that the concentrations of sulfonylureas were saturating both in terms of their effect on membrane potential and in block of whole cell K<sub>ATP</sub> channel currents (Fig. 1). Moreover, the concentration of 8-pCPT-2′-O-Me-cAMP-AM used in the electrophysiological experiments reported here were lower than those used by Leech et al. (2010b). Thus, the ability of 8-pCPT-2′-O-Me-cAMP-AM to potentiate insulin secretion and Ca<sup>2+</sup> transients in our experiments was independent of any enhancement of electrical activity stimulated by the sulfonylureas.

Potentiation of Sulfonylurea-Stimulated Insulin Secretion by 8-pCPT-2′-O-Me-cAMP-AM Involves Ca<sup>2+</sup> Influx via L-type Voltage-Gated Ca<sup>2+</sup> Channels and Enhanced Release of Ca<sup>2+</sup> from Internal Stores. Insulin secretion and Ca<sup>2+</sup> transients (Fig. 2) stimulated by tolbutamide and gliclazide were both blocked by the L-type Ca<sup>2+</sup> channel blocker nicardipine. Moreover, insulin secretion stimulated by both sulfonylureas was substantially blocked by unloading intracellular stores of Ca<sup>2+</sup> with thapsigargin (Fig. 2). Thapsigargin selectively inhibited the early peak of the Ca<sup>2+</sup> transient stimulated by either tolbutamide or gliclazide (Fig. 2). Interestingly, the major effect of 8-pCPT-2′-O-Me-cAMP-AM on sulfonylurea-stimulated Ca<sup>2+</sup> transients was to markedly increase the amplitude of this early peak (Fig. 4). These data suggest that Ca<sup>2+</sup> influx via L-type Ca<sup>2+</sup> channels upon sulfonylurea stimulation of INS-1 cells causes a rapid release of Ca<sup>2+</sup> from internal stores that is greatly amplified by 8-pCPT-2′-O-Me-cAMP-AM via EPAC2. This enhancement of Ca<sup>2+</sup> release is likely the driving factor behind the enhancement of insulin secretion because the concentration threshold of 8-pCPT-2′-O-Me-cAMP-AM for both activities is essentially the same.

Gliclazide, But Not Tolbutamide, Stimulates a Depolarization-independent Activation of Phospholipase C Activity in INS-1 Cells. If tolbutamide were able to directly activate EPAC2 and Rap1 in INS-1 cells, it may have a unique ability to activate phospholipase C-ε and mobilize Ca<sup>2+</sup> from internal stores via an RYR2-independent, phospholipase C/IP<sub>3</sub> receptor-dependent mechanism. We found, however, that both tolbutamide and gliclazide markedly stimulated phospholipase C activity as assessed by accumulation of IP<sub>1</sub>. It was previously reported that glucose stimulates phospholipase C activity that depends upon Ca<sup>2+</sup> influx via L-type Ca<sup>2+</sup> channels and protein kinase C activation in INS-1 cells (Thore et al., 2004). However, our experiments measuring gliclazide- and tolbutamide-stimulated phospholipase C activity in the presence of diazoxide uncovered a unique ability of gliclazide to activate phospholipase C independently of its K<sub>ATP</sub> channel blocking activity (Fig. 5). The mechanism accounting for this activity remains unknown. However, the unique activities of gliclazide that we have identified in this study, including its similarity to carbachol in stimulating IP<sub>1</sub> accumulation in the presence or absence of diazoxide, the partial sensitivity of this activity to pertussis toxin, the ability to stimulate a diazoxide-insensitive Ca<sup>2+</sup> transient, and the ability to stimulate a ryanodine-insensitive Ca<sup>2+</sup> transient in the presence or absence of physiologic concentrations of extracellular Ca<sup>2+</sup> (Fig. 6), suggest that gliclazide may activate a GPCR that stimulates phospholipase C (Fig. 10A). Attractive possibilities include cannabinoid or purinergic receptors. CB<sub>1</sub> and CB<sub>2</sub> receptors are present and coupled to activation of phospholipase C and Ca<sup>2+</sup> mobilization in the rat pancreatic β-cell line RINm5F (De Petrocellis et al., 2007) and mouse pancreatic β-cells (Li et al., 2010). The CB<sub>1</sub> receptor inverse agonists rimonabant and ibipinabant are reported to act as K<sub>ATP</sub> channel openers (Lynch et al., 2012) at low micromolar concentrations, suggesting some similarity in the structural requirements for K<sub>ATP</sub> channel and CB<sub>1</sub> receptors.
lipoprotein in human endothelial cells (Li and Renier, 2009) and to reduce adhesion of monocytes to endothelial cells (Renier et al., 2003)—early steps in atherosclerosis. Determining whether these beneficial effects of gliclazide can be attributed to the non-K\textsubscript{ATP} channel-dependent activity reported here will clearly require further investigation.

The concentrations at which 8-pCPT-2'-O-Me-cAMP-AM began to potentiate insulin secretion (2 \( \mu \text{M} \)) and the first phase of the Ca\textsuperscript{2+} transient stimulated by sulfonylureas (5 \( \mu \text{M} \)) were an order of magnitude below the lowest concentration of 8-pCPT-2'-O-Me-cAMP-AM that activated phospholipase C as detected by the IP\textsubscript{1} assay (50 \( \mu \text{M} \)). A previous study reported activation of phospholipase C activity in INS-1 cells by 10 \( \mu \text{M} \) 8-pCPT-2'-O-Me-cAMP-AM as detected by the translocation of a pleckstrin homology domain/GFP fusion (Leech et al., 2010b). Our data argue that concentrations as low as 2 \( \mu \text{M} \) of 8-pCPT-2'-O-Me-cAMP-AM stimulate PLC activity, which is sufficient to stimulate a rise in intracellular Ca\textsuperscript{2+} concentration, but below the level of detection of the IP\textsubscript{1} HTRF assay. The greater sensitivity of fluorescent Ca\textsuperscript{2+} indicators compared with the IP\textsubscript{1} HTRF assay in detecting the activation of phospholipase C was previously reported (Liu et al., 2008). The 8-pCPT-2'-O-Me-cAMP-AM-stimulated Ca\textsuperscript{2+} rise is sensitive to both 2-APB and removal of extracellular Ca\textsuperscript{2+}, suggesting that influx of Ca\textsuperscript{2+} via a TRP channel may be involved (Fig. 10B). Indeed, inclusion of 5 \( \mu \text{M} \) 8-pCPT-2'-O-Me-cAMP-AM in the pipette solution during voltage-clamp experiments activated an NMDG conductance in the plasma membrane of INS-1 cells (Fig. 7C). Interestingly, several members of the TRP superfamily of cation channels are reported to conduct NMDG, including TRPC (Hillyard et al., 2010), TRPA (Banke et al., 2010), and TRPV (Chung et al., 2008). TRPC channel subtypes are attractive candidates for this activity because they are blocked by 2-APB (Birnbaumer, 2009) and many are positively regulated by PLC activity (Beech, 2012). Interestingly, TRPC1 and TRPC4 are expressed in INS-1 cells and rat \( \beta \)-cells (Li and Zhang, 2009), and TRPC4 is expressed in \( \beta \)TC3 cells (Qian et al., 2002).

In summary, our data show that insulin secretion and Ca\textsuperscript{2+} transients stimulated by gliclazide or tolbutamide are potentiated equally by the EPAC selective cAMP analog 8-pCPT-2'-O-Me-cAMP in INS-1 cells. However, gliclazide, but not tolbutamide, exhibits K\textsubscript{ATP} channel-dependent stimulation of phospholipase C activity that is mediated, in part, by a Gi\textsubscript{q/11}-dependent mechanism. Uncovering differences in activities between gliclazide and other sulfonylureas is of therapeutic relevance because gliclazide has shown some clinical advantages over other second generation drugs. Our data also suggest a potential role for activation of a 2-APB-sensitive Ca\textsuperscript{2+} influx in the EPAC-dependent potentiation of sulfonylurea-stimulated insulin secretion in INS-1 cells. It will be of interest to further characterize this Ca\textsuperscript{2+} flux and identify the channel by which it is conducted.

Authorship Contributions

**Participated in research design:** Hockerman, Jarrard, Wang, Guerra.

**Conducted experiments:** Jarrard, Wang, Guerra, Salyer, Soderling, Pratt, Lange, Broderick.

**Performed data analysis:** Hockerman, Jarrard, Wang, Pratt, Guerra.

**Wrote or contributed to the writing of the manuscript:** Hockerman.

Supplemental Material for MOL # 81943

Supplementary Figure 1. The phospholipase C inhibitor U73122 and the inactive analog U73343 block voltage-dependent Ca\(^{2+}\) channel activity in INS-1 cells- Whole-cell \(I_{\text{Ba}}\) was measured using voltage clamp in the presence or absence of the active phospholipase C inhibitor U73122 or the inactive analog U73343. Cells were clamped at -80mV and currents were elicited by 100ms step to +10mV. Percentage of the whole-cell \(I_{\text{Ba}}\) blocked was measured after compounds were applied for at least 3 minutes and current amplitude reached steady state, and after a washout period of at least 3 minutes. In the presence of 10 μM U73122, \(I_{\text{Ba}}\) amplitude was significantly and irreversibly reduced. ***, \(P < 0.001\) compared to control (n = 5). Increasing the concentration of U73122 to 50 μM did not further reduce the current amplitude. 10 μM U73343 also significantly reduced \(I_{\text{Ba}}\) amplitude, but this inhibition was partially reversible upon washout. ***, \(P < 0.001\) compared to control (n = 5); ***, \(P < 0.001\) compared to 10 μM U73343 before washout (n = 5). (One way ANOVA with Holm-Sidak post-hoc test)
