ABSTRACT

Diuretics are widely used in the treatment of hypertension, although the precise mechanisms remain unknown. Epoxyeicosatrienoic acids (EETs), cytochrome P450 (P450) epoxygenase metabolites of arachidonic acid, play critical roles in regulation of blood pressure. The present study was carried out to investigate whether EETs participate in the antihypertensive effect of thiazide diuretics [hydrochlorothiazide (HCTZ)] and thiazide-like diuretics (indapamide). Male spontaneously hypertensive rats (SHRs) were treated with indapamide or HCTZ for 8 weeks. Systolic blood pressure, measured via tail-cuff plethysmography and confirmed via intra-arterial measurements, was significantly decreased in indapamide- and HCTZ-treated SHRs compared with saline-treated SHRs. Indapamide increased kidney CYP2C23 expression, decreased soluble epoxide hydrolase expression, increased urinary and renovascular 11,12- and 14,15-EETs, and decreased production of 11,12- and 14,15-dihydroxyeicosatrienoic acids in SHRs. No effect on expression of CYP4A1 or CYP2J3, or on 20-hydroxyeicosatetraenoic acid production, was observed, suggesting indapamide specifically targets CYP2C23-derived EETs. Treatment of SHRs with HCTZ did not affect the levels of P450s or their metabolites. Increased cAMP activity and protein kinase A expression were observed in the renal microvessels of indapamide-treated SHRs. Indapamide ameliorated oxidative stress and inflammation in renal cortices by down-regulating the expression of p47phox, nuclear factor-κB, transforming growth factor-β1, and phosphorylated mitogen-activated protein kinase. Furthermore, the p47phox-lowering effect of indapamide in angiotensin II-treated rat mesangial cells was partially blocked by the presence of N-(methylsulfonyl)-2-(2-propynyloxy)benzenemethanamide (MS-PPOH) or CYP2C23 small interfering RNA. Together, these results indicate that the hypotensive effects of indapamide are mediated, at least in part, by the P450 epoxygenase system in SHRs, and provide novel insights into the blood pressure-lowering mechanisms of diuretics.

Introduction

The modern era of diuretic therapy for hypertension began in 1957 when Novello and Sprague synthesized the thiazide diuretic, chlorothiazide. Further modification of the benzothiadiazine core led to the synthesis of hydrochlorothiazide (HCTZ) and the thiazide-like diuretics: chlorothalidone (phthalimidine), metolazone (quinoxalinone), and indapamide (indoline). Indapamide binds and inhibits the Na\(^+\)-Cl\(^-\) cotransporter in the distal convoluted tubule and connecting tubule but does not contain the benzothiadiazine core (Reilly et al., 2010). Despite similarities to other members of the thiazide family, indapamide has unique features that render it a particularly efficacious and advantageous antihypertensive agent (Sasaki et al., 2007).

Indapamide is a relatively weak diuretic that has been shown to produce a significant and sustained reduction in blood pressure with a lower incidence of serious hypokalemia and hyperglycemia (Ambrosioni et al., 1998), and retains efficacy in patients with chronic kidney disease (Madkour et al., 1996). It has been demonstrated to reduce left ventricular hypertrophy to a greater degree than enalapril or atenolol monotherapy (Gosse et al., 2000; de Luca et al., 2004; Dahlof et al., 2005). It is also effective in reducing microalbuminuria in patients with diabetes and hypertension (Puig et al., 2007). Additional mechanisms by which indapamide

ABBREVIATIONS: 20-HETE, 20-hydroxyeicosatetraenoic acid; AA, arachidonic acid; Ang II, angiotensin II; DHET, dihydroxyeicosatrienoic acid; EET, epoxyeicosatrienoic acid; EF, ejection fraction; FS, fractional shortening; HCTZ, hydrochlorothiazide; HEET, hydroxy-EET; k\(\alpha\), inhibitor of \(\kappa\)B; JNK, c-Jun N-terminal kinase; LV, left ventricular; LVESD, left ventricular end-systolic diameter; MAPK, mitogen-activated protein kinase; MS-PPOH, N-(methylsulfonyl)-2-(2-propynyloxy)benzenemethanamide; MDA, malondialdehyde; NF-κB, nuclear factor-κB; P450, cytochrome P450; PKA, protein kinase A; PPAR\(\alpha\), peroxisome proliferator-activated receptor-\(\alpha\); p47phox, soluble epoxide hydrolase; SHR, spontaneously hypertensive rat; siRNA, small interfering RNA; SOD, superoxide dismutase; TGF-β1, transforming growth factor-β1; WKY, Wistar-Kyoto rat.
may exert its antihypertensive effects have been proposed (Sassard et al., 2005). Indapamide induces an increase in the levels of prostacyclin, a cyclooxygenase-derived metabolite of arachidonic acid (AA), in vascular smooth muscle cells (Uehara et al., 1990). This raises the possibility that other AA metabolites may also play a role in the antihypertensive effects of indapamide.

In addition to the cyclooxygenases, AA can be metabolized by enzymes of the cytochrome P450 (P450) superfamily. The P450 epoxygenases generate 5,6-, 8,9-, 11,12-, and 14,15-epoxygenoarachidonic acids (EETs), which are further metabolized to their corresponding less-active dihydroxyeicosatraenoic acids (DHETs) by soluble epoxide hydrolase (sEH) (Fleming, 2001). The P450 ω-hydroxylases produce 20-hydroxyeicosatetraenoic acid (20-HETE) (Zhao and Imig, 2003). Both EETs and 20-HETE are involved in the regulation of vascular function (Zhao and Imig, 2003). Both contribute to the abnormalities in renal function in these animal models.

The CYP2C subfamily enzymes are the major P450 epoxygenases in the kidney. In particular, CYP2C23 is the predominant enzyme expressed in the rat kidney and converts AA to 8,9-EET, 11,12-EET, and 14,15-EET in a ratio of 1:2:1 (Imaoka et al., 1993). Furthermore, CYP2C23 can increase levels of hydroxy-EETs (HEETs) (Muller et al., 2004), which are endogenous activators of peroxisome proliferator-activated receptor-α (PPARα). PPARα activators are also highly expressed in the kidney (Brassant et al., 1996) and exert antioxidant and anti-inflammatory effects (Devchand et al., 1996; Diep et al., 2002; Kono et al., 2009). The production of P450 metabolites in the kidney is altered in rodent models of hypertension such as the spontaneously hypertensive rat (SHR) (Sacerdotti et al., 1989; Yu et al., 2000), and it is likely that changes in this system contribute to the abnormalities in renal function in these models.

In this study, we investigated the possibility that the beneficial effects of indapamide in SHRs may be mediated through induction of P450 enzymes and alterations in levels of EETs or 20-HETE.

**Materials and Methods**

**Animals.** This study was carried out in strict accordance with the recommendations in the Guide for the Care and Use of Laboratory Animals of the National Institutes of Health. The protocol was approved by the Committee on the Ethics of Animal Experiments of the Animal Research Committee of Tongji College. Eleven-week-old male SHRs and Wistar-Kyoto (WKY) rat controls were obtained from the Experimental Animal Center of Beijing (Beijing, China). Rats were treated daily with indapamide (1 mg/kg per day; Servier, Tianjin, China) and HCTZ (20 mg/kg per day; Qingdao Huanghai Pharmaceutical Co., LTD, Qingdao, China), or saline (0.9% NaCl) via gastric gavage for 8 weeks.

**Measurement of Blood Pressure.** Systolic blood pressure was measured every 2 weeks at room temperature using tail-cuff plethysmography as described previously (Xiao et al., 2010). At 8 weeks after drug administration, the rats were anesthetized with pentobarbital (40 mg/kg i.p.) and a microtransducer catheter (SPR-558; Millar Instruments, Inc., Houston, TX) was inserted via the right carotid artery into the left ventricle according to a method described previously to measure blood pressure invasively (Xiao et al., 2010).

**Cardiac Function Study.** Cardiac function was measured by echocardiograph with VIVID 7 (General Electric, Milwaukee, WI), equipped with a 15-MHz linear array ultrasound transducer. Parameters needed for the calculation of cardiac function and dimensions were measured from a minimum of five systole-diastole cycles. Left ventricular end-systolic diameter (LVESD) and left ventricular end-diastolic diameter (LVEDD) were measured from left ventricular (LV) M-mode tracing (with a sweep speed of 50 mm/sec) at the papillary muscle level: LV fractional shortening (FS) and ejection fraction (EF), measures of LV systolic function, were calculated from LV M-mode by the following equations:

\[
FS\% = \left(\frac{LVEDD - LVEDS}{LVEDD}\right) \times 100 \\
EF\% = \left(\frac{LVEDV - LVESV}{LVEDV}\right) \times 100
\]

**Isolation of Thoracic Aortic Rings and Determination of Vascular Function.** Thoracic aortic rings were prepared as described previously (Xiao et al., 2010). We examined the response of aortic rings from rats treated with saline, indapamide or HCTZ to norepinephrine and acetylcholine with a multichannel physiologic recorder (ML-840 PowerLab; ADInstrument Pty Ltd., Bella Vista, NSW, Australia).

**Isolation of Renal Microvessels.** Renal microvessels were isolated according to a method described previously (Imig et al., 2001), collected, rapidly frozen in liquid nitrogen, and stored at -80°C until use.

**Determination of 11,12- and 14,15-DHETs, 11,12- and 14,15-EETs, and 20-HETE in Urine and Tissues.** An enzyme-linked immunosorbent assay kit (Detroit R&D Inc., Detroit, MI) was used to measure the concentrations of 11,12- and 14,15-EETs and their stable metabolites—11,12- and 14,15-DHETs and 20-HETE—in urine and tissues, according to the manufacturer’s instructions. The amount of 11,12- and 14,15-EETs was quantitated by calculating the difference between total acidified 11,12- and 14,15-DHETs and non-acidified 11,12- and 14,15-EETs, respectively, as described (Xiao et al., 2010).

**Western Blotting.** Western blot analysis was performed as described previously (Wang et al., 2003). Antibodies against CYP2C23, CYP2J2, CYP4A1 (Abcam, Cambridge, MA), protein kinase A (PKA), sEH, p47phox, p67phox, mitogen-activated protein kinase (MAPK), p-MAPK, superoxide dismutase (SOD)-1 SOD-2, transforming growth factor-β1 (TGF-β1), p-inhibitor of κBα (IkBα), κBα, nuclear factor-κB (NF-κB), and β-actin (Santa Cruz Biotechnology, Santa Cruz, CA) were used.

**cAMP and Malondialdehyde Assays.** cAMP levels in renal tissues were evaluated using the cAMP XP Assay Kit (Cell Signaling Technology, Beverly, MA), following the manufacturer’s instructions. Renal malondialdehyde (MDA) levels were measured as described previously (Li et al., 2010).

**Evaluation of Renal and Aortic Injury and Cardiac Hypertrophy.** Urinary microalbumin levels were measured using the Rat MALB enzyme-linked immunosorbent assay kit according to the manufacturer’s instructions (Nanjing Jiancheng, Nanjing, China). Kidney sections (6 μm) were stained with sirius red and hematoxylin-eosin. Immunohistochemical detection of CD68 was performed as described previously (Xiao et al., 2010), using CD68 antibody (Santa Cruz Biotechnology, Inc.). Vessel wall collagen was assessed by sirius red staining. Heart sections were stained with hematoxylin-eosin.
Cardiomyocyte diameter and the percentage of interstitial collagen content in the kidney were quantified using the HAIPS Pathologic Imagery Analysis System (Tongji Qianping Image Company, Wuhan, China).

**Effects of Indapamide on CYP2C23 Production in HBZ-1 Cells.** Rat renal mesangial (HBZ-1) cells were transfected with CYP2C23 small interfering RNA (siRNA) (200 nM) or treated with N-(methylsulfonyl)-2-(2-propynoxy)-benzenhexanamide (MS-PP0H), a specific inhibitor of P450 epoxygenase, 10 μM. Transfected or treated cells were incubated with/without indapamide (10 μM) and angiotensin II (Ang II) (100 nM) for 24 hours, after which the cells were collected for western blot analysis.

**Statistical Analysis.** Values of quantitative results were presented as mean ± S.E.M. The data were analyzed with single-factor analysis of variance using GraphPad Prism software (GraphPad Software Inc., La Jolla, CA). Statistical significance was accepted if P < 0.05.

**Results**

**Treatment with Diuretics Lowers Blood Pressure in SHRs.** Administration of indapamide or HCTZ for 8 weeks had no effect on the blood pressure of WKY control rats; however, treatment of SHRs with either drug decreased blood pressure by 16.9 and 15.4 mm Hg, respectively, compared with saline-treated controls (Supplemental Fig. 1A). Prior to sacrifice at the 8-week time point, the carotid intra-arterial pressure was measured, and the results were consistent with the noninvasive tail-cuff measurements (Supplemental Fig. 1B). Moreover, analysis of cardiac hemodynamics showed that dp/dt max was increased in indapamide-treated SHRs compared with saline-treated SHRs (Supplemental Fig. 1C). Measurement of cardiac function by echocardiography showed that EF and FS were increased in indapamide-treated SHRs compared with saline-treated SHRs, but not in HCTZ-treated SHRs (Supplemental Fig. 1, D–E).

**Renal CYP2C23 Expression and 11,12- and 14,15-EET Levels Are Elevated by Indapamide in SHRs.** To investigate whether renal P450s play a role in the antihypertensive effect of indapamide, we quantitatively analyzed the mRNA expression of two P450 epoxygenases, CYP2C23 and CYP2J3, and an ω-hydroxylase, CYP4A1, in the kidney by real-time polymerase chain reaction (Supplemental Table 1). As shown in Fig. 1A, CYP2C23 mRNA levels were upregulated by 2.3-fold in indapamide-treated SHRs compared with saline-treated SHRs, whereas levels of CYP2J3 and CYP4A1 remained unchanged. Treatment with HCTZ had no effect on expression of P450s in the rats. In addition, the protein expression of CYP2C23 was increased in indapamide-treated SHRs (Fig. 1B). Interestingly, both indapamide and HCTZ decreased the protein expression of sEH in SHRs, although indapamide reduced it to a greater degree (Fig. 1B). To estimate P450 activity, levels of 11,12- and 14,15-EETs and 20-HETE were measured. Indapamide increased levels of 11,12- and 14,15-EETs (Fig. 1C) and decreased levels of 11,12- and 14,15-DHETs (Fig. 1D) in the urine of SHRs compared with saline controls. As a result, the EET:DHET ratio was increased by 2.5-fold (Fig. 1E). No significant differences in 11,12- and 14,15-DHETs or 11,12- and 14,15-EETs were observed in HCTZ-treated SHRs or any WKY groups. Meanwhile, the levels of 20-HETE in urine were markedly increased in SHRs compared with WKY rats (Fig. 1F), but were unaffected by treatment with indapamide or HCTZ.

In addition, P450 enzyme expression and EET levels were assessed in renal microvessels. Indapamide increased CYP2C23 expression and decreased sEH expression in SHR microvessels relative to saline controls, while levels of CYP2J3 were not significantly different between the groups (Fig. 2, A–D). Furthermore, treatment of SHRs with indapamide increased and decreased levels of 11,12- and 14,15-EETs (Fig. 2E) and 11,12- and 14,15-DHETs, respectively (Fig. 2F), in the microvessels. No significant differences in 11,12- and 14,15-DHETs or 11,12- and 14,15-EETs were observed in HCTZ-treated SHRs or any WKY groups.

These results suggest that indapamide, but not HCTZ, stimulates CYP2C23 to generate more EETs without affecting the levels of other P450 enzymes and their metabolites.

**Indapamide Increases cAMP Levels and PKA Expression in SHR Renal Microvessels.** The vasodilatory effects of EETs in the renal vasculature have been associated with an increase in cAMP levels and can be blocked by inhibitors of cAMP and PKA signaling (Carroll et al., 2006). To investigate whether these components were altered with indapamide treatment in SHRs, renal microvessels were isolated. Interestingly, both cAMP levels (Fig. 3A) and PKA expression (Fig. 3B) were increased in indapamide-treated SHRs compared with saline-treated SHRs, suggesting that indapamide may increase vasodilation via a cAMP/PKA-dependent pathway. No significant differences in levels of cAMP or PKA were observed in HCTZ-treated SHRs or in any WKY groups.

**Oxidative Stress and Inflammation in the Renal Cortex of SHRs Are Attenuated with Indapamide Treatment.** In addition to increasing EET production, CYP2C23 is known to upregulate the expression of HEETs, endogenous PPARα activators that have both antioxidant and anti-inflammatory properties ( Muller et al., 2004). To investigate whether indapamide affects oxidative stress and inflammation, both of which are commonly observed in SHRs, renal cortices were isolated. Renal tissues from SHRs displayed increased levels of MDA, a marker for oxidative stress (Fig. 4A), and elevated expression levels of two NADPH oxidase subunits (p47phox and p67phox), as compared with that from WKY rats (Fig. 4B). Treatment of SHRs with indapamide or HCTZ significantly decreased levels of MDA (Fig. 4A) and prevented the increase in the expression of p47phox and p67phox (Fig. 4, B and C). SOD-1 and SOD-2 were decreased in SHRs compared with WKY rats, but were markedly increased with HCTZ treatment, while SOD-2 was subtly increased with indapamide treatment (Fig. 4, B and D). In addition, indapamide, but not HCTZ, attenuated renal inflammatory responses by significantly decreasing the expression of CD68 and p65-NF-κB by 25 and 23%, respectively (Fig. 4, E and F). Meanwhile, immunohistochemistry against CD68 showed that indapamide or HCTZ treatment decreased CD68-positive cells relative to the marked increase in saline-treated SHRs (Supplemental Fig. 2A). Furthermore, HCTZ treatment decreased phosphorylated IκBα, while indapamide or HCTZ treatment increased total IκBα expression (Fig. 4F).

Protein levels of TGF-β1 and the phosphorylation of p38 MAPK and c-Jun N-terminal kinase (JNK) were also enhanced in SHRs; treatment with indapamide or HCTZ decreased these effects (Supplemental Fig. 2, B–D). No differences in pro-oxidant or inflammatory factors were observed among WKY groups.
Indapamide Prevents Renal and Aortic Damage and Myocardial Hypertrophy. Renal damage (Feld et al., 1990) and left ventricular hypertrophy are often observed in SHRs. Hematoxylin and eosin staining of renal structures showed that increased solidified glomeruli (a glomerulopathy) in saline-treated SHRs were decreased with indapamide or HCTZ treatment (Supplemental Fig. 3A). Collagen staining of kidney sections revealed that indapamide or HCTZ significantly reduced the renal collagen content in SHRs compared with saline controls (Supplemental Fig. 3, B and C). This was associated with a decrease in albuminuria, suggesting that renal damage is attenuated by indapamide or HCTZ in these hypertensive rats (Supplemental Fig. 3D). Furthermore, measurement of serum creatinine by picric acid showed that the increased serum creatinine seen in saline-treated SHRs was decreased by treatment with indapamide or HCTZ significantly.
Analysis of collagen in the aorta cell wall showed that indapamide or HCTZ treatment decreased collagen deposition in the intima-media and ameliorated oxidative stress (Supplemental Fig. 4, A and B). Measurement of vascular function by artery rings showed that contraction in response to norepinephrine decreased, and dilation in response to acetylcholine increased in aortic rings from HCTZ- and indapamide-treated SHRs compared with SHR controls (Supplemental Fig. 4C). We also evaluated the degree of myocardial hypertrophy in SHRs by measuring cardiomyocyte diameter in hematoxylin and eosin–stained heart sections and calculating the ratio of left ventricular weight:body weight (mg/g). A marked reduction in cardiomyocyte diameter (Supplemental Fig. 5E) and the ratio of left ventricular weight:body weight (Supplemental Fig. 5C) was observed in indapamide-treated SHRs compared with saline-treated SHRs, suggesting that indapamide also attenuates myocardial hypertrophy in hypertension.

**Indapamide-Induced Reduction of p47phox Is CYP2C23-Dependent in HBZY-1 Cells.** To confirm the role of CYP2C23 in the effects of indapamide in the kidney, we evaluated the Ang II–induced increase in p47phox expression in rat mesangial (HBZY-1) cells that were either treated with MS-PPOH, a specific P450 epoxygenase inhibitor, or
transfected with CYP2C23 siRNA. A 50% reduction in CYP2C23 protein was achieved in CYP2C23 siRNA-transfected cells. Treatment of control HBZY-1 cells with Ang II significantly increased the expression of p47phox and p67phox. Addition of indapamide to these cells decreased the Ang II-mediated induction in p47phox and p67phox expression. However, the p47phox or p67phox-lowering effect of indapamide was partially blocked in cells treated with MS-PPOH (Fig. 5, A and B), which also exhibited significant decreases in CYP2C23 expression (Fig. 5C). These results further suggest that the antioxidant effects of indapamide are mediated via CYP2C23 in the kidney.

**Discussion**

This study was undertaken to investigate the effect of indapamide on blood pressure in hypertensive rats and the mechanisms involved. The results showed that indapamide reduced blood pressure in SHRs and altered the expression of renal CYP2C23 and sEH, leading to increases in EETs and decreases in DHETs. Indapamide did not have significant effects in WKY control rats. Interestingly, HCTZ decreased blood pressure in the SHRs to a similar degree as indapamide, but failed to affect renal P450 expression or production of EET/s/DHETs in either urine or renal tissue. These results imply that CYP2C23-derived EETs may be involved in the antihypertensive effect of indapamide, but not of HCTZ.

CYP2C isoforms are considered to be the major arachidonic acid epoxygenases in the kidney. In particular, CYP2C23 is the major epoxygenase expressed in rat kidney and converts AA to 8,9-, 11,12-, and 14,15-EET (Holla et al., 1999). Among these, 11,12-EET is the most active vasodilator in the preglomerular vasculature (Imig et al., 1996a) and a potent anti-inflammatory epoxide (Node et al., 1999). Induction of CYP2C23 not only increases the levels of EETs, but also stimulates the endogenous PPARα activator, HEET (Müller et al., 2004). PPARα is highly expressed in the kidney (Braissant et al., 1996) and exerts both antioxidant and anti-inflammatory effects (Devchand et al., 1996; Diep et al., 2002; Kono et al., 2009). These characteristics, combined with our observations, suggest that the hypotensive effects of indapamide may be due, at least in part, to increases in CYP2C23 expression and EET production.

EETs have been identified to be endothelium-derived hyperpolarizing factors (Campbell et al., 1996) and the predominant products generated by a rat CYP2C23 present in isolated renal microvessels (Imig et al., 2001). The current study shows that indapamide increased CYP2C23 expression and 14,15-EET levels in renal microvessels of SHRs. Indapamide also decreased sEH expression, which may have a synergistic effect with CYP2C23 in increasing 14,15-EET production and decreasing the levels of DHETs, which are less active in the vasculature (Imig et al., 1996a). Previous studies have demonstrated that 11,12-EET analogs increase cAMP but not CGMP levels (Imig et al., 2008) and also that EETs dilate renal arteries by activating renal smooth muscle cell Ca<sup>2+</sup>-activated K<sup>+</sup> channels (Zou et al., 1996), which are dependent on PKA activation (Imig et al., 1999). Our data showed that treatment of SHRs with indapamide also increased cAMP levels and PKA expression in isolated renal microvessels. It is possible that these changes in cAMP and PKA may increase dilation in the renal vasculature, thus leading to a decrease in blood pressure.

It is well known that renal oxidative stress, inflammation, and hypertension are highly interrelated (Rodriguez-Iturbe et al., 2001; Vaziri, 2004; Touyz, 2005); modulating any one of them could affect the status of the other two (Nava et al., 2003; Rodriguez-Iturbe et al., 2003). Meanwhile, antioxidants are known to reduce blood pressure in SHRs (Nava et al., 2003; Rodriguez-Iturbe et al., 2003), and NF-κB blockade reduces oxidative stress and blood pressure in SHRs (Elks et al., 2009). A recent study showed that expression of NADPH oxidase subunits, p47phox and p67phox, is upregulated in the kidneys of SHRs (Chabrashvili et al., 2002). In addition, studies have shown that SOD activity is suppressed in SHRs (Ito et al., 1995; Ushiyama et al., 2004). SOD, catalyzing the dismutation of unstable superoxide anions to H<sub>2</sub>O<sub>2</sub>, acts as the first line of defense against reactive oxygen species. Thus, treatment with SOD mimetics decreases superoxide anion...
production and attenuates the development of hypertension in SHRs (Schnackenberg et al., 1998). The data presented in this study indicate that indapamide ameliorated oxidative stress in the renal cortex of SHRs, potentially by decreasing p47phox and p67phox expression and increasing SOD expression. It also attenuated renal inflammatory responses by decreasing p65-NF-κB expression, which may be associated with the anti-inflammatory effects of 11,12-EET or HEETs.

Oxidative stress can trigger the activation of redox-sensitive signal transduction pathways such as those that

Fig. 4. The effects of indapamide or HCTZ on oxidative stress and inflammation in the renal cortex. Renal cortices were isolated from SHRs and WKY rats treated with saline, indapamide (IDP), or HCTZ. (A) MDA levels were measured as an indicator of oxidative stress, using a commercial assay kit. N = 5; *P < 0.05 versus saline-treated WKYs; **P < 0.05 versus saline-treated SHRs. Representative western blots (B) and corresponding densitometry analyses (C–F) of p47phox, p67phox, SOD-1, SOD-2, CD68, p65-NF-κB, p-IκBα, and IκBα. N = 3, duplicated three times; *P < 0.05 versus saline-treated WKYs; **P < 0.05 versus saline-treated SHRs.
include NF-κB, which in turn intensifies oxidative stress (Vaziri and Rodriguez-Iturbe, 2006) and upregulates JNK and p38 MAPK pathways (Hehner et al., 2000). Moreover, JNK and p38 MAPK play important roles in renal fibrosis, acting downstream of TGF-β1. Previous studies showed that blockade of JNK abrogates the pathogenesis of interstitial fibrosis (Ma et al., 2007) and a p38 MAPK inhibitor reduces extracellular matrix production in the rat kidney (Stambe et al., 2004). The
role of TGF-β1 in renal fibrosis is widely accepted (Schnaper et al., 2002). Enhanced expression of TGF-β1 has been shown to contribute to the development of renal fibrosis in hypertensive rats (Gallego et al., 2001). The present study revealed that indapamide treatment reduced renal collagen deposition, decreased levels of TGF-β1, and inhibited the activation of p38 and JNK in the renal cortex of SHR, suggesting that indapamide may reduce renal inflammation and fibrosis by decreasing oxidative stress and MAPK activation. Furthermore, indapamide attenuated oxidative stress by increasing CYP2C23 expression in vitro in HBZY-1 cells, which was partially abrogated by addition of MS-PPOH, a specific P450 epoxygenase inhibitor, or transfection with CYP2C23 siRNA.

In summary, the present study provides evidence that activation of the CYP2C23 epoxygenase pathway may be involved in the antihypertensive effect of indapamide. These data suggest that indapamide increases EET production via the induction of CYP2C23 and the inhibition of sEH. EET ameliorates the hypertension observed in SHR by increasing cAMP and PKA expression in the renal microvessels and decreasing expression of the NADPH oxidase subunits p47phox, p67phox, NF-xB, and TGF-β1 in the renal cortex. However, HCTZ decreased blood pressure and ameliorated the oxidative stress and inflammation in the renal cortex without activates the P450 epoxygenase pathway, which will be investigated in the future.
