ABSTRACT

Aquaporins (AQPs) in the major intrinsic family of proteins mediate fluxes of water and other small solutes across cell membranes. AQP1 is a water channel, and under permissive conditions, a nonelective cation channel gated by cGMP. In addition to mediating fluid transport, AQP1 expression facilitates rapid cell migration in cell types including colon cancers and glioblastoma. Work here defines new pharmacological derivatives of bumetanide that selectively inhibit the ion channel, but not the water channel, activity of AQP1. Human AQP1 was analyzed in the Xenopus laevis oocyte expression system by two-electrode voltage clamp and optical osmotic swelling assays. The aquaporin ligand bumetanide derivative AqB011 was the most potent blocker of the AQP1 ion conductance (IC50 of 14 μM), with no effect on water channel activity (at up to 200 μM). The order of potency for inhibition of the ionic conductance was AqB011 > AqB007 > AqB006 > AqB001. Migration of human colon cancer (HT29) cells was assessed with a wound-closure assay in the presence of a mitotic inhibitor. AqB011 and AqB007 significantly reduced migration rates of AQP1-positive HT29 cells without affecting viability. The order of potency for AQP1 ion channel block matched the order for inhibition of cell migration, as well as in silico modeling of the predicted order of energetically favored binding. Docking models suggest that AqB011 and AqB007 interact with the intracellular loop D domain, a region involved in AQP channel gating. Inhibition of AQP1 ion conductance could be a useful adjunct therapeutic approach for reducing metastasis in cancers that upregulate AQP1 expression.

Introduction

Osmotic water transport across biologic membranes is facilitated by membrane proteins known as aquaporins (AQPs), which are found in all kingdoms of life (Reizer et al., 1993; Park and Saier, 1996; Campbell et al., 2008). To date, at least 15 mammalian subfamilies have been identified: AQP0–AQP14 (Ishibashi, 2009; Finn et al., 2014). Aquaporin is organized as a tetramer of subunits, each comprising six transmembrane domains and five loops (A–E) and carrying a monomeric pore that allows the movement of water or other small solutes (Jung et al., 1994; Fu et al., 2000; Sui et al., 2001).

There is increasing recognition that certain classes of aggressive cancers depend on upregulation of AQP1 for fast migration and metastasis (Monzani et al., 2007). Although the precise mechanism for AQP1-enhanced motility remains unknown, both ion and water channels are essential in the cellular migration process (Schwab et al., 2007). AQP1 expression has been linked to metastasis and invasiveness of colon cancer cells (Jiang, 2009; Yoshida et al., 2013). In mammary and melanoma cancer cells, AQPs facilitate tumor cell migration in vitro and metastasis in vivo (Hu and Verkman, 2006). Increased levels of AQP1 expression in astrocytoma correlate with the clinical grade, serving as a diagnostic indicator of poor prognoses (El Hindy et al., 2013). AQP1-facilitated cell migration in glioma cannot be substituted by AQP4, indicating more than a simple water channel function is involved in the migration-enhancing mechanism (McCoy and Sontheimer, 2007).

A subset of aquaporins have been shown to have ion channel function, including AQP0, AQP1, AQP6, plant nodulin, and Drosophila big brain (Yool and Campbell, 2012). In AQP1, multiple lines of evidence have shown the cGMP-dependent monovalent cation channel is located in the central pore at the 4-fold axis of symmetry and is pharmacologically distinct from the monomeric water pores (Anthony et al., 2000; Saparov et al., 2001; Boassa and Yool, 2003; Yu et al., 2006; Zhang et al., 2007). The AQP1 ion channel has a unitary conductance of 150 pico siemens in physiologic saline, slow activation and deactivation kinetics, and is permeable to Na+, K+, and Cs+, but not divalent cations (Yool et al., 1996; Anthony et al., 2000). Loop D has been shown previously to be involved in the migration-enhancing gating of AQP1 ion channels (Yu et al.,...
MgCl₂, 1.8 mM CaCl₂, and 5 mM HEPES, pH 7.3) to allow protein

Oocyte Preparation and Injection. The use of animals in this
study has been carried out in accordance with the Guide for the Care
and Use of Laboratory Animals, licensed under the South Australian
Animal Welfare Act 1985, with protocols approved by the University of
Adelaide Animal Ethics Committee. Unfertilized oocytes were har-
vored from anesthetized Xenopus laevis frogs and defolliculated by
incubation in type 1A collagenase (2 mg/ml) with a trypsin inhibitor
(0.3 mg/ml) in OR-2 saline (82 mM NaCl, 2.5 mM KCl, 1 mM MgCl₂,
and 5 mM HEPES; pH 7.3) at 16
...potency blocks AQP1 water permeability by covalent modifi-
cation of a cysteine residue in loop E (Preston et al., 1993), but
is highly toxic. The tetrathylenimonium ion blocks the AQP1
water pore, although not in all cell types (Brooks et al., 2000;
Detmers et al., 2006; Sogaard and Zeuthen, 2008), and the
cadmium ion blocks the AQP1 ion channel (Boassa et al.,
2006), but both lack selectivity for aquaporins. Effective
compounds discovered recently include the aroylsulfonamides
AqB013, which blocks AQP1 and AQP4 water channel per-
meability (Migliati et al., 2009), and AqF026, which strongly
potentiates AQP1 water channel activity (Yool et al., 2013).
Other aroylsulfonamides have been proposed as blockers of
AQP4 channels (Huber et al., 2009). A distinct class of agents
acting on the external side of the membrane to block human
AQP1 water flux has been identified as a source of candidate
lead compounds for drug development (Seeliger et al., 2013).

Work here characterizes a novel set of aquiraporin ligand
bumetanide derivative (AqB) compounds that differentially
block the AQP1 ion channel without affecting water perme-
ability. The most potent of these, AqB011, is a promising tool
for dissecting the role of the AQP1 ion channel while sparing
osmotic water permeability. Understanding the functional
roles and regulation of AQP1 is essential for determining the
full range of physiologic roles it might serve and its possible
value as a therapeutic target in cancer metastasis.

Materials and Methods

Oocyte Preparation and Injection. The use of animals in this
study has been carried out in accordance with the Guide for the Care
and Use of Laboratory Animals, licensed under the South Australian
Animal Welfare Act 1985, with protocols approved by the University of
Adelaide Animal Ethics Committee. Unfertilized oocytes were har-
vored from anesthetized Xenopus laevis frogs and defolliculated by
incubation in type 1A collagenase (2 mg/ml) with a trypsin inhibitor
(0.3 mg/ml) in OR-2 saline (82 mM NaCl, 2.5 mM KCl, 1 mM MgCl₂,
and 5 mM HEPES; pH 7.3) at 16°C for 2 to 3 hours. Human
aquaporin-1 cDNA was provided by Professor P. Agre (Preston et al.,
1992; GenBank accession number NM_198098). AQP1 subcloned into
a X. laevis β-globin plasmid was linearized with BanHI and trans-
scribed in vitro (T3 mMessage mMachine; Ambion Inc., Austin, TX),
and cRNA was resuspended in sterile water. Prepared oocytes were
injected with 50 nl of water (non–AQP1 expressing control oocytes)
or 50 nl of water containing 1 ng of AQP1 cRNA and incubated for 2 or
more days at 16°C in ND96 saline (96 mM NaCl, 2 mM KCl, 1 mM
MgCl₂, 1.8 mM CaCl₂, and 5 mM HEPES, pH 7.3) to allow protein
expression. Successful expression was confirmed by osmotic swelling
assays. Batches of AQP1-expressing oocytes that lacked robust
cGMP-activated conductance responses were further incubated
overnight in ND96 saline with the tyrosine phosphatase inhibitor
bisperoxovanadium (100 μM; Santa Cruz Biotechnology, Dallas, TX)
per published methods (Campbell et al., 2012). Chemicals were
purchased from Sigma-Aldrich (St. Louis, MO) unless otherwise
specified.

AqB Compounds: Synthesis and Preparation. The AqB com-
ounds (custom-designed bumetanide derivatives) were synthesized
by Dr. G. Flynn (Spacefill Enterprises LLC, Oro Valley, AZ) as
described in U.S. patent 8,835,491-B2. To make AqB001, bumetanide
was mixed with diazomethane (CH₂N₂) generated by reaction with
Diazald to create bumetanide methyl ester [molecular weight (MW)
344.8; ClogP 2.10], which was dissolved in hot CHCl₃, diluted with
hexanes and allowed to cool to provide the purified methyl ester as
white flakes, whose mass and NMR spectra were consistent with the
desired product. Reaction of bumetanide with 1.2 equivalents of 1,1-
carboxyldimidazole in ethyl acetate (EtOAC) under argon with
heating afforded an intermediate imidazolidine, which upon cooling,
formed a white solid that could be isolated by filtration and stored
under argon for later use. Alternatively, the imidazolidine solution
could be reacted in situ with two equivalents of an amine to form the
remaining imidazoline. In a typical reaction, the reaction mixture
would be partitioned between water and EtOAC, the organic layer
would be washed with brine, the solution would be filtered and
concentrated, and the residue would be crystallized to form EtOAc-
hexanes. AqB-006 (MW 413.9; ClogP 1.04) was prepared using morpholine as the amine; AqB007 (MW 470.0; ClogP 0.79) resulted
from 2,4-(methylpiperezine-1-yl) ethylamine; and AqB011 (MW 434.9;
ClogP 1.80) was prepared using 2-(morpholine-1-yl)ethylamine. The
structures of all the compounds were confirmed by high-resolution
mass spectrometry and NMR analysis. Chemicals were purchased
from Sigma-Aldrich unless otherwise specified.

Powdered compounds were dissolved in dimethylsulfoxide (DMSO)
to create 1000× stock solutions for each desired final dosage. An equal
dilution of DMSO (0.1%) alone in saline was used as the vehicle
control.

Quantitative Swelling Assay. For double-swelling assays, each
oocyte served as its own control. Swelling rates were assayed first
without drug treatment (S1), and then oocytes incubated for 2 hours in
isotonic saline with or without the AqB compounds were reassessed in
a second swelling assay (S2). Swelling rates in 50% hypotonic saline
(isotonic Na saline diluted with an equal volume of water) were
quantified by relative increases in the oocyte cross-sectional area
imaged by videomicroscopy (charge-coupled device camera; Cohu,
San Diego, CA) at 0 for 3 minutes and (S2) for 30 seconds.

Electrophysiology. For the two-electrode voltage clamp, capill-
ary glass electrodes (1–3 MΩ) were filled with 1 M KCl. Recordings
were done in standard Na⁺ bath saline containing 100 mM NaCl,
2 mM KCl, 4.5 mM MgCl₂, and 5 mM HEPES, pH 7.3. cGMP was
applied extracellularly at a final concentration of 10–20 μM using the
membrane-permeable cGMP analog (Rp-8-(para-chlorophenylthio-
)cGMP. Ionic conductance was monitored for at least 20 minutes after
cGMP addition to allow development of maximal plateau responses.
Conductance was determined by voltage step protocols from +60 to
−110 mV from a holding potential of −40 mV. Recordings were made
with a GeneClamp amplifier and pClamp 9.0 software (Molecular
Devices, Sunnyvale, CA).

Circular Wound Closure Assay. The cancer cell lines used in
this study were HT29 human colorectal adenocarcinoma cells (Chen
et al., 1987) purchased from American Type Culture Collection (ITB-
38; Manassas, VA), which strongly express endogenous AQP1, and
SW480 human colorectal adenocarcinoma cells (CCL-228; from
American Type Culture Collection), which express AQP5 but show
little AQP1 expression. mRNA levels were evaluated by quantita-
tive polymerase chain reaction and protein levels by western blot
(H. Dorward et al., submitted manuscript). Confluent cultures of
HT29 and SW480 cells were used in migration assays to measure the effects of AqB treatments on rates of wound closure. Cells were plated at 10^4 cells/well in 96-well plates, and fluorescence signal was measured with a FLUOstar Optima microplate reader (BMG Labtech, Victoria, Australia) after 24-hour incubation, with concentrations of AqB011 ranging from 1 to 80 M, to obtain quantitative measures of cell viability. Mercuric chloride (20 M) was used as a positive control for cytotoxicity.

Molecular Modeling. In silico modeling was conducted with methods reported previously (Yool et al., 2013). The crystal structure of human AQP1 was obtained from the Protein Data Bank (PDB) (identity 1FQY). The tetrameric model (Supplemental Material) was generated in PyMol (Version 1.7.4; Schrödinger, LLC; Mannheim, Germany) using coordinates provided in the pdb file. Renderings of the AqB ligands were generated in Chemdraw (Version 13.0; PerkinElmer, MA) and then converted into the pdb format using the online SMILES translation tool (National Cancer Institute, U.S. Department Health and Human Services, Washington, DC). Both AQP1 and ligand coordinates were prepared for docking using MGLtools (Version 1.5.4; Scripps Institute, San Diego, CA). The docking was carried using Autodock Vina (Trott and Olson, 2010), with a docking grid covering the intracellular face of tetrameric pore.

Data Compilation and Statistics. The results compiled from replicate experiments are presented as box plots. The boxes represent 50% of the data, the error bars indicate the full range, and the horizontal bars are the median values. The n values are in italics above the x-axis. Statistical differences were analyzed with one-way analysis of variance and post hoc Bonferroni tests and reported as *P < 0.0001, *P < 0.05, and N.S. (P > 0.05).

Results

AQP1 Ion Channel Inhibition by Novel Bumetanide Derivatives. A set of four related compounds with structural modifications at the carboxylic acid moiety of bumetanide was tested for effects on the cGMP-activated ionic conductance in AQP1-expressing oocytes. Two-electrode voltage clamp recordings of AQP1-expressing oocytes (Fig. 1) illustrate the inhibition of the ionic conductance by extracellular application of AqB007 (200 M) and AqB011 (20 M), but no appreciable block of the AQP1 ion channel with 200 M AqB001 or AqB006. Initial recordings before cGMP application and responses to the first application of cGMP recordings showed typical cGMP-dependent activation, as described previously (Anthony et al., 2000). Oocytes were then transferred into saline with the indicated agents for 2 hours, during which time the ionic conductances uniformly recovered to initial levels (Fig. 2). In response to the second application of cGMP, oocytes treated with vehicle (DMSO), AqB001, or AqB006 showed increases in conductance that were comparable to the first response. However, the cGMP-activated conductance responses were inhibited after treatment with AqB007 or AqB011.

Trend plots (Fig. 2A) show that the ionic conductance in AQP1-expressing oocytes was initially low and activated by the first bath application of membrane-permeable cGMP. The ionic conductance then recovered to the basal level during 2-hour incubation without cGMP and was tested for reactivation by a second application of cGMP after treatment with vehicle or AqB compounds. Recordings for oocytes incubated in saline without DMSO during the recovery period were comparable to

![Fig. 1. Chemical structures of selected bumetanide derivatives and electrophysiology traces showing representative effects of AqB001, AqB006, AqB007, and AqB011 on the ionic conductance responses activated by bath application of CPT-cGMP before and after 2-hour incubation in saline with and without the AqB compounds. See Materials and Methods for details.](image-url)
those for the DMSO-treated group (not shown). Non–AQP1-expressing control oocytes showed no ionic conductance response to cGMP and no effect of the vehicle or drug treatments (Fig. 2B).

Compiled data for the cGMP-activated ionic conductance values in AQP1-expressing oocytes are shown in the box plot (Fig. 3A) and indicate the levels of block by 200 μM AqB007 and 20 μM AqB011 were statistically significant as compared with initial responses to cGMP prior to treatment. Dose-response relationships (Fig. 3B) yielded estimated IC₅₀ values of 14 μM for AqB011 and 170 μM for AqB007.

Fig. 2. Trend plots showing the ionic conductance responses for individual oocytes measured prior to cGMP (initial), after the first cGMP application, after 2-hour incubation in saline without cGMP containing DMSO (vehicle) or AqB agents, and after the second application of cGMP. Reversible cGMP-dependent activation of an ionic conductance in AQP1-expressing oocytes (A) was not seen in non-AQP1 control oocytes (B). Inhibition was seen after treatment with AqB007 and AqB011, but not with vehicle, AqB001, or AqB006.

AqB Ion Channel Blockers Have No Effect on Osmotic Water Permeability. Data for oocyte volumes that were standardized as a percentage of the initial volume at time zero illustrate the mean swelling responses over 60 seconds after introduction of the oocytes into 50% hypotonic saline (Fig. 4A). AQP1-expressing oocytes showed consistent osmotic swelling, which was unaffected by treatment with vehicle (DMSO 0.1%) or AqB compounds at 200 μM each. Non–AQP1-expressing control oocytes showed little osmotic water permeability.

To analyze the possible effects of the AqB compounds on water channel activity, a double-swelling assay was used (Fig. 4B).
After the first swelling (S1) in hypotonic saline, oocytes were incubated in isotonic saline with or without the AqB compounds (200 μM) for 2 hours before assessing the second swelling response (S2). There were no significant differences between the first and second swelling rates in any of the treatment groups, confirming that the AqB ion channel agents did not affect AQP1 osmotic water permeability.

**Molecular Modeling of Candidate Intracellular Binding Sites.** Putative binding sites on the AQP1 ion pore for AqB011 and AqB007 in the intracellular loop D domain can be suggested based on structural modeling and docking analyses (Fig. 5). In silico modeling suggested the sites for the most favorable energies of interaction for AqB007 and AqB011 were located at the intracellular face of the central pore (Fig. 5A). Interestingly, the model predicted hydrogen bonding between the uniquely elongated moieties of the two effective AqB ligands and the initial pairs of arginine residues in the highly conserved loop D motifs from two adjacent subunits (Fig. 5B). The same arginines (R159 and R160 in human AQP1) have been shown to be involved in AQP1 ion channel gating, but not water channel activity, in prior work (Yu et al., 2006). The more compact AqB006 docked weakly at a different position in the central vestibule (not shown). Although in silico modeling does not define actual binding sites, it provides a testable hypothesis for future work and offers intriguing support for the role of loop D in modulating AQP1 ion channel gating. The most
cancer cell migration did not impact cell viability. AqB011 at doses used to block the AQP1 ionic conductance and cell death, which was measured as a decrease in fluorescence. 80 μM of AqB011 treatment on HT29 cells at concentrations of up to 24 hours confirmed there was no appreciable cytotoxic effect. The persistence of the fluorescent signal HT29 cells (Table 1). Cell viability was assessed with untreated cells and no effect of treatment with AqB011 for no significant difference in the viability of vehicle-treated and effect of AqB011 appears to be selective for AQP1. express AQP5, but not AQP1, suggesting that the inhibitory the migration rate of SW480 colon cancer cells (Fig. 6B), which in blocking migration, which is consistent with the relative conductance. In contrast, AqB011 at 100 μM had no effect on migration rate of SW480 colon cancer cells (Fig. 6B), which express AQP5, but not AQP1, suggesting that the inhibitory effect of AqB011 appears to be selective for AQP1.

**AqB Compounds Show Low Cytotoxicity.** There was no significant difference in the viability of vehicle-treated and untreated cells and no effect of treatment with AqB011 for HT29 cells (Table 1). Cell viability was assessed with alamarBlue assays. The persistence of the fluorescent signal at 24 hours confirmed there was no appreciable cytotoxic effect of AqB011 treatment on HT29 cells at concentrations of up to 80 μM. Mercuric chloride as a positive control caused significant cell death, which was measured as a decrease in fluorescence. AqB011 at doses used to block the AQP1 ionic conductance and cancer cell migration did not impact cell viability.

**Discussion**

The aim of this study was to search for selective small-molecule pharmacological agents that are capable of blocking the cGMP-activated cationic conductance in AQP1. Discovery of pharmacological modulators for AQP1 channels has been an important goal in the aquaporin field. AQP1 antagonist and agonist agents are expected to be useful for defining the complex roles of aquaporins in fundamental biologic processes as well as characterizing AQP1 modulators as potential clinical agents in various conditions, such as cancer metastasis (Yool et al., 2010). AQP1 expression is upregulated in subtypes of aggressive cancer cells, in which it facilitates cancer migration. The results here show that selective blockers of the AQP1 ion channel slow the migration of human colon cancer cells in culture. Pharmacological inhibition of AQP1 is predicted to have a protective effect in reducing metastasis in cancer, but remains to be demonstrated in vivo.

Using bumetanide as a starting scaffold, we created an array of novel synthetic derivatives. Based on pilot data indicating a small inhibitory effect of AqB050 on the AQP1 ion channel at high doses (unpublished data), we investigated a series of structurally related derivatives, AqB006, AqB007, and AqB011, as well as a simple methylated version of bumetanide, AqB001, to test for possible inhibitors of the AQP1 ion conductance. Our findings demonstrated that AqB007 and AqB011 are effective inhibitors of the central ion pore of AQP1, with estimated IC₅₀ values of 170 and 14 μM, respectively. Both AqB007 and AqB011 showed dose-dependent inhibition of the central ion pore, whereas the intrasubunit water pores were unaffected, enabling the first dissection of physiologic roles of the distinct channel functions. Measuring fluorescence signal intensity with the alamarBlue

cell viability assay showed that AqB011 was not cytotoxic at doses that produced maximal ion channel inhibition.

The inhibition by AqB011 of AQP1 ionic conductance was consistent with molecular docking studies, suggesting the site of interaction is at the intracellular face of the central pore. The results revealed that AqB011 is the most energetically favored compound, followed by AqB007. The predicted interaction site of AqB011 and AqB007 with AQP1 is at the loop D domain. Differences in the structures and efficacies of AqB006, AqB007, and AqB011 indicate that the structure-activity relationship of ion channel inhibition is sensitive to specific chemical modifications at the carboxylic acid position of bumetanide. The length and structure of the modification appears to be critical and based on in silico modeling to be the region that interacts with the AQP1 channel gating loop D domain. The absence of cytotoxic effects of AqB011 at doses sufficient to block the AQP1 ion channel activity indicates that the inhibition of migration is not indirectly due to cell death. The observation that AqB011 inhibited migration in AQP1-expressing HT29 colon cancer cells, but had no effect on the migration of AQP5-expressing SW480 colon cancer cells, provides support for the idea that AqB011 is selective for AQP1. The inhibition of migration seen with AqB011 is unlikely to result from off-target effects on general metabolic function, cytoskeletal organization, actin polymerization, or signaling pathways involved in cell motility since SW480 cell migration remained unaffected by the presence of AqB011.

AQP1 is present in barrier epithelia involved in fluid movement in the body, including the proximal tubule and choroid plexus (Agre et al., 1993). It is also expressed in peripheral microvasculature, dorsal root ganglion cells, eye ciliary epithelium and trabecular meshwork, heart ventricles, and other regions, in which a direct role for osmotic water flux is less evident (Yool, 2007). Additional roles suggested for AQP1 include angiogenesis (Nicchia et al., 2013), signal transduction (Oshio et al., 2006), increased mechanical compliance to changes in pressure (Baez et al., 2009), axonal regeneration of spinal nerves (Zhang and Verkman, 2015), recovery from injury (Hara-Chikuma and Verkman, 2006), and exocytosis (Arnaoutova et al., 2008). Relative contributions of the ion and water channel functions in these diverse processes remain to be defined.

A possible role for the AQP1 ionic conductance (potentially in combination with water fluxes) in the control of cell volume associated with migration was supported by the results of the wound closure assays with AQP1-expressing HT29 cells. Cell migration was significantly impaired by AqB011 and AqB007, but not by AqB006. The greatest efficacy of migration block was seen with administration of AqB011. The comparable orders of efficacy for the block of AQP1 ion channels in the oocyte expression system and for the block of cell migration in HT29 cultures support the idea that the AqB011 effect on migration is mediated by direct block of the AQP1 ion channels. These data provide evidence that the ion channel activity of AQP1 has physiologic relevance. Further work is needed to evaluate the effects of blocking both water and ion channel activities of AQP1 together in migrating cells.

AqB011 is a new research tool for probing the physiologic role of the AQP1 ion channel function in biologic systems. This compound holds future promise as a possible adjunct clinical intervention in cancer metastasis. Exciting opportunities are likely to emerge from continuing discovery of pharmacological modulators for aquaporins for new treatments and other diseases.
