Abstract

Telomere repeat binding factor 2 (TRF2) has been increasingly recognized to be involved in DNA damage response and telomere maintenance. Our previous report found that salvicine (SAL), a novel topoisomerase II poison, elicited DNA double-strand breaks and telomere erosion in separate experimental systems. However, it remains to be clarified whether they share a common response to these two events and in particular and if TRF2 involves in this process. In this study, we found that SAL concurrently induced DNA double-strand breaks, telomeric DNA damage and telomere erosion in lung carcinoma A549 cells. Unexpectedly, SAL led to disruption of TRF2, independently of either its transcription or proteasome-mediated degradation. By over-expressing the full-length *trf2* gene and transfecting TRF2 small interfering RNAs, we showed that TRF2 protein protected both telomeric and genomic DNA from the SAL-elicited events. Notably, though both the Ataxia-telangiectasia-mutated (ATM) and the ATM- and Rad3-related (ATR) kinases responded to the SAL-induced DNA damages, only ATR was essential for the telomere erosion. The study also showed that the activated ATR augmented the SAL-triggered TRF2 disruption while TRF2 reduction in turn enhanced ATR function. All these findings suggest the emerging significance of TRF2 protecting both telomeric DNA and genomic DNA on one hand, and reveal the mutual modulation between ATR and TRF2 in sensing DNA damage signaling during cancer development on the other hand.

MOL#39081

Introduction

Telomere is the specialized ribonucleoprotein structure at the ends of chromosomes in eukaryotic cells, which specifically protects chromosomes from end fusion and genomic instability (Greider and Blackburn, 1996). Thus, telomere integrity in cells thus plays an essential role in the control of genomic stability. Dysfunction of telomeres leads to cell cycle arrest and initiates cell apoptosis or cell senescence (Farazi et al., 2006; Herbig and Sedivy, 2006; Lechel et al., 2005). Therefore, an increasing numbers of studies have focused on telomere maintenance.

Telomere maintenance depends heavily on telomere binding proteins, of which telomere repeat binding factor 2 (TRF2) is a critical member. TRF2 is one of six proteins consisting of the protein complex shelterin (de Lange, 2005). Shelterin has been shown to be located on telomeres and to be related to telomere length regulation and telomere structure maintenance (de Lange, 2005). However, recent reports have revealed that TRF2 is recruited to DNA double-strand break (DSB) sites immediately after DSBs take place (Bradshaw et al., 2005). The TRF2 protein is phosphorylated in response to DSB signals (Tanaka et al., 2005). Loss or mutation of TRF2 leads not only to telomeric structure destruction but also to DNA damage, apoptosis or senescence concomitantly (Lechel et al., 2005; Smogorzewska and de Lange, 2002; van Steensel et al., 1998; Wang et al., 2004). In addition, TRF2 promotes the polymerization activity of DNA polymerase β (pol β) on telomeric and non-telomeric DNA substrates (Muftuoglu et al., 2006). As such, TRF2 is emerging

MOL#39081

as a potential target in cancer therapy.

Salvicine (SAL) is a novel diterpenoid quinone compound synthesized by the structural modification of a natural product isolated from the Chinese medicinal herb *salvia prionitis lance* (Zhang et al., 1999). It is now undergoing its phase II clinical trials. SAL possesses potent *in vitro* and *in vivo* activities against malignant tumor cells (Qing et al., 1999) functioning as a noninteractive topoisomerase II (Top2) poison (Lu et al., 2005a; Lu et al., 2005b; Meng et al., 2001a). Moreover, SAL stimulates intracellular reactive oxygen species (ROS), which subsequently elicits DNA DSBs closely related with cell death (Lu et al., 2005b). Furthermore, SAL inhibits telomerase activity and shortens telomere length in a telomerase-independent manner (Liu et al., 2002; Liu et al., 2004). Due to the notion that the telomere erosion is critical for DNA DSBs, we have investigated whether tumor cells share the common response to telomeric and non-telomeric DNA damage upon the exposure to salvicine. In particular, as TRF2 is increasingly recognized to be capable of functionally sensing DNA damage, we further investigated if TRF2 is involved in salvicine-triggered telomere erosion and DNA DSBs.

The aim of the present study is to unravel the effect of SAL on genomic and telomeric DNA in a single system, to characterize the role of SAL on TRF2 expression, and to explore the possible involvement of TRF2 protein in SAL-driven events. This will hopefully further our understanding of the distinct or unidentified roles of TRF2 in cancer development.

MOL#39081

Materials and Methods

Drugs and chemicals. SAL was provided by the Department of Phytochemistry in the Shanghai Institute of *Materia Medica* of the Chinese Academy of Sciences. The purity of the compound was more than 99%. VP16 and caffeine were purchased from the Sigma Chemical Co. (St. Louis, USA). MG-132 was the product of the Biomol Biotech. Inc. (Plymouth Meeting, USA). Both SAL and VP16 were prepared at 100 mM in DMSO. Caffeine was dissolved at 80 mM in distilled water and then filtrated with 0.22 μm filter (Millipore, USA). MG-132 was dissolved at 20 mM in DMSO. The aliquots of SAL, VP16 and caffeine stock solutions were stored at -20°C , and MG-132 stock solution was kept in -80°C avoiding light. All drugs were diluted to desired concentrations in full medium immediately prior to each experiment. The final DMSO concentrations did not exceed 0.1%.

Cell culture. A549 cells were obtained from the American Type Culture Collection (ATCC, Manassas, USA) and cultured in Ham's F12 medium (GIBCO BRL, Grand Island, USA) supplemented with 10% (v/v) heat-inactivated fetal bovine serum (GIBCO BRL, Grand Island, USA), 100 $\mu\text{g}/\text{mL}$ of streptomycin, 100 units/mL of penicillin and 2 mM L-glutamine in a humidified atmosphere (5% CO_2) at 37°C .

Comet assays. DNA DSBs were evaluated using the neutral single cell gel electrophoresis (neutral comet assays) as previously described (Olive et al., 1990) with minor modifications (Lu et al., 2005a). Quantification was performed by analyzing at least 50 randomly- selected comets per slide with the Komet 5.5 software

MOL#39081

(Kinetic Imaging Ltd., Nottingham, UK). The Olive tail moment (OTM) was selected as the parameter that best reflects the degree of DNA damage (arbitrary units, defined as the product of the percentage of DNA in the tail multiplied by the tail length), and the data were expressed as mean \pm SD.

Relative telomere length assays. Relative telomere length was detected by flow cytometry (FLOW-FISH) via fluorescence *in situ* hybridization with a fluorescein-conjugated PNA probe using the Telomere PNA Kit/FITC for Flow Cytometry (DAKO, Glostrup, Denmark) according to the manufacturer's protocol with a slight modification (Liu et al., 2004). Relative telomere length was the ratio of the telomere fluorescence intensity in treated cells to that in the control; the telomere fluorescence intensity = (Mean FL1 with probe – mean FL1 without probe). The fluorescence intensity of the control cells was taken as 100%.

Telomere FISH and TUNEL assays. Cellular telomere signals and DNA break signals were detected with the Cy3-labeled telomere PNA probe and the FITC-labeled dUTP respectively. Using the Telomere PNA FISH kit (DAKO, Glostrup, Denmark), telomere signals were performed first. Cells were cultured and treated on chamber slides in 6-well plates and then fixed in 4% paraformaldehyde in PBS for 15 min. Following washing with PBS, the cells were permeabilized in 0.1% TritonX-100 for 10 min and washed again with PBS. The slides were immersed in the pre-hybridization solution for 10 min and subsequently in cold ethanol series (70%, 85% and 95%) and left in air until dried. Fifty μ L TUNEL reaction mixture containing the FITC-labeled

MOL#39081

dUTP and terminal deoxynucleotidyl transferase (TdT) (Roche, Switzerland) was added to the slides. After incubation at 37°C for 1 h, the slides were washed three times with PBS, air-dried and stained with 0.5 µg/mL DAPI for 30 min in the dark. Images were taken using a Leica TCS Confocal Microscope (Leica, Deerfield, USA).

Western blot analyses. Protein levels were measured by Western blotting with corresponding specific primary antibodies, including those against TRF2 (Imgenex, USA), phosphorylated-H2AX (γ-H2AX) (Cell signal Biotech., USA), Ataxia-telangiectasia-mutated kinase (ATM) (Rockland Inc., USA), ATM- and Rad3-related (ATR) (Calbiochem, USA) and Myc (Cell signal Biotech., USA). Shown were the representative data from separate experiments.

Immunofluorescence assays. A549 cells plated on coverslips in 24-well plates were used to study the subcellular localization of TRF2 and γ-H2AX. Cells were air-dried, fixed for 30 min with 4% paraformaldehyde in PBS (pH 7.4), and washed twice with PBS. Then, the cells were incubated for 15 min with 0.2% TritonX-100 and washed with PBS. After that, the cells were incubated in blocking buffer [3% bovine serum albumin (BSA) in PBS] for 30 min before being incubated for 1 h with the primary antibodies against TRF2 (Imgenex, USA) and γ-H2AX (Cell Signal, USA). Following three washes (2 min each) with PBS, the cells were incubated for an additional 1 h with the Alexa Fluor[®] 488-conjugated secondary antibody (Alexa Fluor[®] 488 goat anti-mouse IgG, Molecular Probes, USA). The cells were washed three times and stained with 0.5 µg/mL DAPI for 30 min in the dark. Images were taken using a

MOL#39081

Leica TCS Confocal Microscope (Leica, Deerfield, USA). Fluorescence was semi-quantitated by Photoshop 7.0 software.

RNA extraction and RT-PCR. Total cellular RNA was isolated from A549 cells with the RNeasy Mini Kit (Qiagen, German) using the standard protocol for animal cells. The semi-quantitative reverse transcription-PCR (RT-PCR) for *trf2* mRNA was performed with the QIAGEN OneStep RT-PCR Kit. *Trf2* primers used were 5'-TCC CAA AGT ACC CAA AGG C-3'(sense) and 5'-ACT CCA GCC TTG ACC CAC TC-3'(antisense). GAPDH was used as the loading control with the primers of 5'-TCA CCA TCT TCC AGG AGC GAG A-3' (sense) and 5'-GCA GGA GGC ATT GCT GAT GAT C-3' (antisense). The Onestep RT-PCR program was run as the following: for the reverse transcription, 50°C for 30 min and 95°C for 15 min; and for the PCR, hot start 94°C for 2 min followed by 36 cycles of 94°C for 30 s, 60°C for 30 s and 72°C for 45 s, and then 72°C, 10 min. The PCR products were resolved by 1.5% agarose electrophoresis.

Telomere-ChIP. ChIP was carried out using a Chromatin IP (ChIP) assay kit, following the manufacturer's instructions (Upstate, USA). Cells were fixed with formaldehyde for 10 min and then sonicated. Sonicated samples were pre-cleared and precipitated with the TRF2 antibody (Imgenex, USA). The resulting precipitates (ppt) were blotted onto a Hybond-N membrane (Amersham Biosciences, USA) under vacuum. Aliquots of the supernatants before immunoprecipitation were taken out as inputs. Telomere repeat sequences were detected with a TeloTAGGG telomere length

MOL#39081

assay kit (Roche Diagnostics, Switzerland). Briefly, the membrane was hybridized with a DIG-labeled telomere probe. The hybridized telomeric DNA was probed with the anti-DIG antibody. Telomere signals were semi-quantitated with InGenius Bio-Imaging System (Syngene, Cambridge, UK). Telomeric DNA in CHIP (%) = Telomeric DNA signal of ppt / Telomeric DNA signal of input \times 100%.

Construction of recombinant expression plasmids : *pCDNA3.1-myc-his(-)A-trf2* and *pCDNA3.1-myc-his(-)A-trf2^{ABAM}*. *pBabe puro-trf2* and *pBabe puro-trf2^{ABAM}* were taken as the template plasmids, which were kind gifts from Professor de Lange Titia in the Rockefeller University. The full-length *trf2* gene was amplified by PCR with two primers carrying EcoR I and BamH I sites: 5'-GTG CTG GAT ATC TGC AGA ATT CCA ATG GCG GGA GGA GGC GGG AGT AGC G-3' (sense) and 5'-CTT GGT ACC GAG CTC GGA TCC GTT CAT GCC AAG TCT TTT CAT GGT CCG CC-3' (antisense). The *trf2^{ABAM}* PCR primers with EcoR I and BamH I sites used for amplification were 5'-GTG CTG GAT ATC TGC AGA ATT CCA ATG GAG GCA CGG CTG GAA GAG GCA GTC A-3' (sense) and 5'-CTT GGT ACC GAG CTC GGA TCC TTC TAC AGT CCA CTT CTG CTT TTT TGT TA-3' (antisense). Eighty ng template plasmids were added to a 50 μ L PCR system, including 1 \times buffer [10 mM Tris-HCl (pH8.3), 1.5 mM MgCl₂, 50 mM KCl], 50 μ M dNTPs, 3 units of Taq DNA polymerase, and 0.1 μ M of specific primers. The PCR mixture was subjected to 30 cycles of 94°C for 30 s, 55°C for 30 s and 72°C for 1 min. The amplified products were digested with EcoR I and BamH I and ligated to the

MOL#39081

corresponding cloning sites in the *pcDNA3.1/myc-His(-)A* mammalian expression vector (Invitrogen, USA).

Transfection of plasmids and selection for stable expression cell lines. The plasmids were transfected with Lipofectamine 2000 (Invitrogen, USA). For each transfection, 4 μ L lipofectamine 2000 was added to 200 μ L opti-MEM and incubated at room temperature for 5 min. The mixture was then added to further 200 μ L opti-MEM with 2 μ g plasmid DNA for 20 min. The transfection complexes were then applied to cells within 600 μ L opti-MEM medium. After 4 h incubation, 1 mL fresh F12 medium was added to the cells. Twenty-four hours later, the medium was replaced with fresh full medium. Subsequently, positive transfected cells were selected with 500 μ g/mL G418. The Myc tag was detected by Western blotting.

Small interfering RNA (siRNA) and transfection. Three pairs of TRF2 siRNA sequences were designed as #1: 5'-CCU UCU UUA GUG GUU UGC UUA UdTdT-3' (sense) and 5'-AUA AGC AAA CCA CUA AAG AAG GdTdT-3' (antisense); #2: 5'-ACC UAA UUU CAU UCU UUG UGA AdTdT-3' (sense) and 5'-UUC ACA AAG AAU GAA AUU AGG UdTdT-3' (antisense); #3: 5'-CGG CUU UCA UUU CCA CAG AAU UdTdT-3' (sense) and 5'-AAU UCU GUG GAA AUG AAA GCC GdTdT-3' (antisense). Their target sequences are all located within the 3'-UTR region of the TRF2 cDNA(#1: nts.2199-2220; #2: nts. 2702-2723; #3: nts. 1633-1653). ATR siRNA sequences were 5'-CCU CCG UGA UGU UGC UUG AdTdT-3' (sense) and 5'-UCA AGC AAC AUC ACG GAG GdTdT-3' (antisense)

MOL#39081

(Casper et al., 2002). ATM siRNA sequences were 5'-CAU ACU ACU CAA AGA CAU UdTdT-3' (sense) and 5'-AAU GUC UUU GAG UAG UAU GdTdT-3' (antisense) (Nur et al., 2003). All the RNA oligonucleotides and the mock siRNAs were synthesized by the Genepharma Co. (Shanghai, CHINA). siRNAs were transfected with the Oligofectamine reagent (Invitrogen, USA) according to the manufacturer's instructions.

Sulforhodamine B (SRB) assays. The sensitivity of A549 cells to SAL was evaluated by SRB assays (Lu et al., 2005a). The cell proliferation inhibition rate was calculated as: proliferation inhibition (%) = $[1 - (A_{515 \text{ treated}}/A_{515 \text{ control}})] \times 100\%$.

***In vitro* assays for ATR kinase activity.** ATR kinase assays with immunoprecipitated ATR from A549 cells were carried out as described previously (Canman et al., 1998) with minor modifications. After treatment, cells were trypsinized and washed three times in cold PBS and the pellets were lysed for 10 min at 4°C in 200 µL lysis buffer [25 mM HEPES (PH 7.4), 300 mM NaCl, 5 mM EGTA, 1 mM MgCl₂, 0.5% NP-40, 10 µg/mL aprotinin, 1 µg/mL pepstatin A, 10 µg/mL leupeptin, 2 mM PMSF, 20 nM microcystin-LR, 25 mM NaF]. Pre-cleared lysates were incubated with the ATR primary antibody (Calbiochem, USA) and protein A/G agarose at 4°C overnight. The complexes were washed three times with lysis buffer and then twice with kinase reaction buffer [50 mM HEPES (pH 8.0), 10 mM MnCl₂, 2.5 mM EDTA, 1 mM DTT]. The beads were then re-suspended in 30 µL of kinase reaction buffer containing 10 mM ATP and 5 µg p53 recombinant protein (Lab Vision Corporation,

MOL#39081

Fremont, USA). The mixture was incubated at 30°C for 30 min. Then 30 µL of 2×SDS loading buffer was added and the phosphorylated proteins were separated by SDS–PAGE, then proceeding for normal Western blotting with the anti-phospho-p53(Ser15) antibody (Cell signal Biotech., USA). Bands of phospho-p53 were scanned and semi-quantitated with the InGenius Bio-Imaging System (Syngene, Cambridge, UK). The activity of ATR in the mock-siRNA-alone group was taken as 100%.

Statistical analyses. All the data are represented as mean values \pm SD. The significance of differences between means was assessed by Student's *t* test, with $P<0.05$ and $P<0.01$ considered statistically significant.

MOL#39081

Results

SAL induces both DNA DSBs and telomeric erosion in A549 cells. To detect whether SAL concurrently induces both DNA DSBs and telomeric erosion, we treated A549 cells with different concentrations of SAL for 3 h. Using Comet assays, we found that SAL elicited DNA DSBs as shown by “comet tails” in neutral electrophoresis (Fig. 1A). The degree of DNA DSBs was augmented as the concentrations of SAL increased (Fig. 1A). The increase of the γ -H2AX levels and the formation of γ -H2AX foci in the SAL-treated A549 cells further confirmed the result from Comet assays (Fig. 1B). These data indicate that SAL produces genomic DSBs and activates a DNA damage response in A549 cells.

At the same time, SAL also damaged and shortened telomeric DNA. Using the telomere-specific probe and dUTP-FITC to label telomeric DNA and DNA breaks, respectively, their co-localization was defined as DNA break foci at telomere sites (Bradshaw et al., 2005; Karlseder et al., 2004). From Fig. 1C, the co-localization of DNA break signals and telomere signals appeared in the cells treated with 25 μ M SAL. With increasing concentrations of SAL, DNA breaks were observed across the nuclei in a diffuse pattern and DNA damage at telomere sites increased concurrently. Moreover, as the concentrations of SAL increased from 25 μ M to 100 μ M, the relative telomere length reduced progressively from 87.7 ± 6.6 % to 53 ± 1.5 % (Fig. 1D). The data above demonstrate that SAL can induce both telomeric and non-telomeric DNA damage in A549 cells.

MOL#39081

SAL disrupts TRF2 protein in A549 cells. TRF2 protein has been shown to bind to telomeric DNA and protects the structure of telomeres (Stansel et al., 2001; Yoshimura et al., 2004). Release of TRF2 from telomeres would leave the telomeric DNA unprotected (Li et al., 2005). In addition, TRF2 has also been suggested to be related to non-telomeric DNA damage and DNA repair events (Bradshaw et al., 2005; Muftuoglu et al., 2006; Tanaka et al., 2005). Using immunofluorescence microscopy, dot blotting and Western blotting, we found that SAL dramatically reduced the TRF2 protein levels in A549 cells (Fig. 2A). However, the levels of *trf2* mRNA did not change before and after SAL treatment (Fig. 2B *upper*). The proteasome inhibitor MG-132 also could not reverse the SAL-induced down-regulation of TRF2 protein, although MG-132 apparently enhanced the level of hypoxia-induction factor 1 α (HIF-1 α) that is known to be degraded *via* the proteasome pathway (Li et al., 2004) (Fig. 2B *lower*). Therefore, such reduction in TRF2 protein was irrelevant to TRF2 transcription or to TRF2 degradation *via* the proteasome pathway (Fig. 2B). We further detected the ratio of the telomeric DNA bound to TRF2 relative to the total telomeric DNA using telomere-ChIP assays. SAL was shown to significantly decrease the telomeric DNA bound to TRF2, from 83.6 ± 2.4 % to 48.7 ± 1 % (Fig. 2C), indicating that some TRF2 was released from telomeric DNA. The data above suggest that SAL is likely to potentiate damage to telomeric and genomic DNA by disrupting the protection mechanism based on TRF2 protein.

TRF2 attenuates SAL-induced DNA damage and telomere erosion. To clarify

MOL#39081

the involvement of TRF2 to SAL-elicited DNA damage events, we over-expressed TRF2 and down-regulated TRF2 expression using its small interfering RNAs (siRNAs). The myc-tagged full length *trf2* constructs and the basic/myb domain double-deficient *trf2-bm* constructs (van Steensel et al., 1998) were transfected into A549 cells and over-expressed effectively (Fig. 3A). Comet assays (Fig. 3B) and γ -H2AX detection (Fig. 3C) showed that the full length *trf2* transfection produced fewer DSBs and lower levels of γ -H2AX in A549 cells following the treatment with SAL compared to the vector transfection. Moreover, the telomere shortening (Fig. 3D) and cytotoxicity (Fig. 3E) induced by SAL were also rescued by the full length *trf2* transfection. In contrast, the double-deficient *trf2-bm* transfection, which would exert a dominant-negative-like action (Smogorzewska and de Lange, 2002; van Steensel et al., 1998), enhanced the genotoxic effects of SAL (Figs. 3B~E). These data show that over-expression of TRF2 can protect cells from SAL-induced DNA damage and telomere erosion.

On the other hand, we detected the effects of three TRF2 siRNAs with different sequences in A549 cells. All the target sequences are located in the 3'-UTR of *trf2* gene. Among them, the #2 TRF2 siRNA elicited the most prominent down-regulation of TRF2 expression 24 h post transfection (Fig. 3F) and was chosen for the subsequent experiments. The TRF2 siRNA transfection resulted in higher levels of γ -H2AX (Fig. 3G) and more severe erosion of telomeres (Fig. 3H) induced by SAL than the mock siRNA transfection. Our results indicate that the reduction of TRF2

MOL#39081

potentiates DNA DSBs and telomere shortening in response to genotoxic stress.

Taken together, our data from TRF2 over-expression and down-regulation experiments suggest that TRF2 protein provides cells abilities to prevent telomeric and non-telomeric DNA from genotoxic insults with a protection mechanism.

The DNA damage sensor ATR is required for the cellular response to the SAL-induced DNA damage and telomere shortening. TRF2 has been suggested to be coupled with DNA damage response (Bradshaw et al., 2005; Tanaka et al., 2005). The protein kinases ATM and ATR are two key sensors for DNA damage signaling (McGowan and Russell, 2004). To investigate how TRF2 protein is involved in DNA damage events following SAL exposure, we firstly detected whether ATM and ATR function in the SAL-induced DNA damage. Caffeine, an inhibitor for both ATM and ATR (Blasina et al., 1999; Sarkaria et al., 1999; Zhou et al., 2000), nearly eliminated SAL-induced γ -H2AX (Fig. 4A) and completely rescued telomeres from SAL-induced erosion (Fig. 4D). However, only the down-regulation of ATR with siRNA totally prevented the SAL-induced H2AX phosphorylation and telomere erosion in A549 cells (Fig. 4C and 4E); ATM siRNA only reduced the levels of γ -H2AX and marginally eased telomere shortening in the SAL-treated cells (Fig. 4B and 4E). The data suggest that ATR is likely to play a more crucial role than ATM in the cellular response to SAL-elicited DNA damage, especially to SAL-induced telomere-erosion. However, both kinases may be required for the cellular response to SAL-elicited DNA damage.

MOL#39081

TRF2 knockdown potentiates ATR activation, and ATR knockdown prevents the TRF2 reduction following the treatment with SAL. The data above show that TRF2 reduction is involved in DNA damage events induced by SAL and that ATR is a critical factor for both DSBs and telomeric erosion elicited by SAL. In order to investigate how TRF2 protein is involved in DNA damage events, we studied the relationship between TRF2 and ATR. Firstly, we examined the change of ATR activity following TRF2 knockdown. In the mock siRNA group, SAL enhanced the ATR activity by about 1.0 fold. Surprisingly, TRF2 knockdown by siRNA led to an additional 0.4 fold increment in the ATR activity in response to the SAL treatment (Fig. 5A). We then investigated the effect of ATR knockdown on TRF2 loss induced by SAL. The immunofluorescence of TRF2 showed that ATR knockdown by siRNA unexpectedly rescued the loss of TRF2 protein resulted from the treatment with SAL (Fig. 5B). These data suggest there might be a close relationship of mutual regulation between the protein TRF2 and the kinase ATR, which is worthy of being studied further.

MOL#39081

Discussion

We previously reported that SAL elicited DNA DSBs (Lu et al., 2005a; Meng and Ding, 2001; Meng et al., 2001a; Meng et al., 2001b) and telomere erosion (Liu et al., 2004) in separate systems. In the present study, using a single system in which SAL did not induce early apoptosis (data not shown), we found that there exists a common cellular response mechanism to both DNA DSBs and telomere erosion in SAL-initiated events, i.e., SAL concurrently elicited both genomic DNA DSBs and telomere erosion in A549 cells. Further studies highlight that this dual action, driven by SAL, is in a TRF2-involved and ATR-mediated manner.

In tumor cells, the telomere length depends on the activity of telomerase, which functions mainly in S phase during DNA replication. If the telomerase activity was inhibited, telomere would shorten in the subsequent cell cycles, which would be a long-term event. The other reason for telomere shortening is breakage in telomere DNA, which can result from oxidative damage (von Zglinicki et al., 2000). Although SAL inhibited telomerase activity after short-term treatment, it is obviously not the main factor to shorten telomere within 3 h (Liu et al., 2004). Moreover, the co-localization of DNA damage signals and telomere signals showed that the DNA damage signals at the sites of telomeres increased with the concentrations of SAL (Fig 1C), suggesting that the main reason for the rapid telomeric DNA loss induced by SAL could result from the DNA breakage inside telomere structure. Any telomere dysfunction resulting from mutation of telomere binding proteins, telomerase

MOL#39081

inhibition and destruction of telomere structure, would induce end-to-end fusion of chromosomes in tumor cells. Abnormal chromosomes due to telomere dysfunction would be harmful to the whole genome and activate DNA damage checkpoints, which would activate apoptosis and inhibit cellular proliferation (Farazi et al., 2006; Herbig and Sedivy, 2006; Lechel et al., 2005). Therefore, telomere erosion elicited by SAL in short-time might be one important reason for the final fate of tumor cells, such as proliferation inhibition and apoptosis under SAL treatment (Liu et al., 2004; Lu et al., 2005a; Qing et al., 1999).

TRF2 is an important telomere binding protein; its deletion or mutation leads to the loss of the telomeric 3'-tail and fusion of chromosome ends (Klapper et al., 2003; Lechel et al., 2005; Li et al., 2005; Smogorzewska and de Lange, 2002; van Steensel et al., 1998; Wang et al., 2004). TRF2 over-expression attenuates the ionizing irradiation-initiated DNA damage response to DSBs and inhibits the ionizing irradiation-induced cell cycle arrest in primary human fibroblasts (Bradshaw et al., 2005; Karlseder et al., 2004). In our study, by either over-expression of wild-type or mutated TRF2 or knockdown of TRF2 with its specific siRNAs, we demonstrate that TRF2 protects telomeric and non-telomeric DNA from SAL-induced damage (Fig. 3). In addition to its protective impact on telomere structure (Griffith et al., 1999; Yoshimura et al., 2004), TRF2 is also implicated in DNA damage and DNA repair systems (Bradshaw et al., 2005; Karlseder et al., 2004; Muftuoglu et al., 2006; Tanaka et al., 2005; Zhu et al., 2000). In fact, TRF2 was capable of being translocated to

MOL#39081

ionizing irradiation-produced non-telomeric DSB sites and being phosphorylated in an ATM-dependent manner (Bradshaw et al., 2005; Tanaka et al., 2005). TRF2 has been shown to interact with the MRE11/RAD50/NRE repair complex and to stimulate the activity of the repair enzyme DNA polymerase β (Muftuoglu et al., 2006; Zhu et al., 2000). Moreover, it has been reported that TRF2 is required for repair of non-telomeric DNA DSBs by homologous recombination (Mao et al., 2007). As such, we propose that the SAL-elicited TRF2 disruption might deprive the cells of protection, favoring shortening of telomere, and thus aggravation of DNA damage.

The protein kinases ATM and ATR are critical for DNA damage response (McGowan and Russell, 2004). Their activation depends on the type of DNA damage. Irradiation (IR) or other extracellular stimuli which elicit DSBs usually activate ATM kinase (Shiloh, 2003). ATR has been shown usually activated by replication protein A (RPA)-binding single-strand (Zou and Elledge, 2003). However, our studies show that not only ATM but also ATR were involved in SAL-induced DNA DSBs (Fig.4), as demonstrated that ATR could also respond to DSBs. Furthermore, our data is consistent with the recent report that both ATM and ATR are activated in response to IR-induced DSBs or UV-elicited DNA SSBs. And they activate different downstream substrates in the DNA damage response systems (Helt et al., 2005). Therefore, the involvement of ATR in SAL-induced DSBs might be explained that ATR phosphorylates certain substrates that cooperate with ATM in response to DSBs resulting from SAL.

MOL#39081

Given the fact that ATM and ATR are critical for DNA damage response (McGowan and Russell, 2004), and ATM has been shown to mediate TRF2 phosphorylation (Tanaka et al., 2005), which in turn inhibits ATM activity in a direct manner (Celli and de Lange, 2005; Karlseder et al., 2004), we investigated the possibility of a mutual regulation of both ATM and ATR in TRF2-driven events. By using siRNA tools, we unexpectedly observed only ATR but not ATM is required for SAL-elicited telomere erosion (Fig 4). Although further studies are needed with ATM or ATR deficient cell lines, these data partially suggested an alternative view where the activation of ATR and ATM might play an unequal role, at least in part, in SAL-induced telomeric damage. The reason that ATM lacks its active commitment to the TRF2-mediated telomeric DNA damage in response to SAL remains unclear, which also deserves further investigation.

In addition, our findings that down-regulation of TRF2 by its specific siRNA led to the enhanced activation of ATR induced by SAL, together with the fact that the ATR siRNA transfection prevented the reduction of TRF2 in response to SAL treatment, suggest a mutual negative feedback between the active ATR and TRF2 in tumor development. We propose there are two possible mechanisms for the interaction between ATR and TRF2. The first is that TRF2 might inhibit ATM activation (Denchi and de Lange, 2007; Karlseder et al., 2004) as ATM could regulate upstream ATR activation (Yoo et al., 2007); consequently, TRF2 indirectly induces ATR repression. The other possible mechanism is that ATR might regulate the

MOL#39081

expression of TRF2 protein, suggested to be mediated by certain crosstalk between their signal pathways. However, the detailed interaction between TRF2 and ATR still needs to be investigated. This will go beyond the significance of SAL in cancer therapy.

In summary, SAL concurrently induces telomeric and non-telomeric DNA damage in A549 cells. The DNA damage activates the sensor kinase ATR, followed by disruption of TRF2, which in turn negatively regulates ATR activation in response to SAL. As a consequence, TRF2 reduction allows the genomic DNA and telomeres to avoid the protection related to TRF2, thus potentiating the genotoxicity and anticancer activity of SAL. This study provides the first line of evidence of TRF2 disruption in sensing DNA damage, and suggests the potential mutual regulation between ATR and TRF2. With further research, it is likely that a connection between telomere maintenance and DNA damage response in cancer development will be elucidated.

Figure Legends

Figure 1. SAL concurrently induces DNA double-strand breaks and telomeric

erosion. **A.** A549 cells were treated with 25, 50 μ M SAL or 100 μ M VP16 for 3 h and were harvested for detection of DNA double-strand breaks (DSBs) by neutral comet assays. Representative “comet” images (200 \times) (*left*) from 3 separate experiments were shown in which DNA was stained with DAPI (*blue*). Results were semi-quantitated with the Komet 5.5 software and expressed as the Olive tail moment (*right*). **B.** Phosphorylation of the histone H2AX (γ -H2AX) in the SAL-treated A549 cells. *left*: the levels of γ -H2AX protein detected by Western blotting; *right*: Formation of γ -H2AX foci (*green*) examined by immunofluorescence confocal microscopy. Nuclear outlines were superimposed using the respective DAPI images. **C.** The damage sites on telomeric DNA. A549 cells were treated with 25, 50 μ M SAL for 3 h. Telomere signals were detected with a Cy3-labeled telomere PNA probe (*red*); DNA breaks were presented with FITC-labeled dUTP (*green*). The DNA break sites colocalized with the telomeres after SAL treatment (*right*), *bar* = 5 μ m. **D.** Telomere shortening was induced by SAL. Telomere length was detected by Flow-FISH with a fluorescein-conjugated PNA probe. Representative histograms of flow cytometry from 3 independent experiments (*left*) were revealed. Relative telomere length was expressed as mean \pm SD (*right*). Relative telomere length was the ratio of the telomere fluorescence intensity in treated cells to that in the control; the telomere fluorescence intensity = (Mean FL1 with probe – mean FL1 without probe). The

MOL#39081

fluorescence intensity of the control was taken as 100%.

Figure 2. SAL disrupts TRF2 protein in A549 cells. **A.** Reduction of TRF2 protein by SAL. A549 cells were exposed to 50 μ M SAL for 3 h and then subjected to immunofluorescence confocal microscopy (*left*, *bar*=4 μ m), dot blotting (*middle*) and Western blotting (*right*). GAPDH was used as the loading control. Quantification for the Western blotting data was done with Adobe Photoshop 7.0.1. **B.** SAL-induced reduction of TRF2 protein was independent of the expression of TRF2 mRNA (*upper*) and the degradation of TRF2 protein *via* the proteasome pathway (*lower*). The levels of TRF2 mRNA were analyzed by RT-PCR. To detect the degradation of TRF2 protein *via* the proteasome pathway, A549 cells were treated with 50 μ M SAL for 3 h following pre-exposure to 10 μ M MG-132 for 1 h, then subjected to Western blotting to detect TRF2 (lower left) and Hif 1 α (lower-right) protein level. **C.** Reduction of the telomeric DNA bound to by TRF2. Telomere-CHIP assays were performed using a TRF2 antibody to examine the telomeric DNA bound to by TRF2. *upper*: Telomeric DNA signals were detected with the DIG-labeled telomere probe from the Roche TeloTAGGG telomere detection system. Input: Supernatant before immunoprecipitation; ppt: Protein-DNA immunoprecipitate complex. Normal mouse IgG was used as the negative control. *Lower*: Telomere signals were semi-quantitated with InGenius Bio-Imaging System. Telomeric DNA in CHIP (%) = Telomeric DNA signals of ppt / Telomeric DNA signals of input \times 100%.

MOL#39081

Figure 3. TRF2 attenuates SAL-induced DNA damage and telomere erosion. A.

Over-expression of TRF2. *Upper:* Schematic diagrams of human TRF2 and the predicted products of different Myc-tagged *trf2* alleles. *Lower:* Myc-tagged TRF2 proteins detected by Western blotting in total cell extracts from the monoclonal A549 cell population surviving over G418 selection post transfection. **B.** TRF2 over-expression decreased the SAL-induced DSBs examined by neutral gel electrophoresis assays. ($\# p < 0.01$ vs Vector without SAL group, $**p < 0.01$ vs Vector with SAL group). **C.** Reduced generation of γ -H2AX by SAL in TRF2 over-expressed cells examined by Western blotting (*left*) and by confocal microscopy (*right*). **D.** TRF2 over-expression prevented SAL-elicited telomere shortening. Telomere fluorescent signals of the groups without SAL treatment were taken as 100%. Relative telomere length of the corresponding SAL-treated groups was calculated as the ratio of their fluorescence to that of their counterpart. The results were expressed as means \pm SD, n=3 ($*p < 0.05$). **E.** TRF2 over-expression protected cells from SAL's cytotoxicity measured by SRB assays. **F.** TRF2 knockdown 24 h post transfection with 200 nM of siRNAs with different sequences. The relative density of bands was analyzed with InGenius Bio-Imaging System. **G.** TRF2 down-regulation enhanced the production of γ -H2AX by the SAL treatment. A549 cells were transfected with 200 nM siRNA for 24 h followed by the exposure to 50 μ M SAL or 100 μ M VP16 for 3 h. Western blotting was done to test the levels of γ -H2AX. **H.**

MOL#39081

TRF2 knockdown aggravated the telomere shortening elicited by SAL. Telomere fluorescence signals in the mock siRNA group without SAL were taken as 100%.

Figure 4. ATR is required for the cellular response to the SAL-induced DNA damage and telomere shortening. **A.** Caffeine prevented the phosphorylation of the histone H2AX. A549 cells were treated with 50 μ M SAL for 3 h following the pretreatment with 2 mM caffeine for 1 h and subjected to Western blotting (*left*) and to immunofluorescence confocal microscopy (*right*). **B.** ATM siRNA alleviated the phosphorylation of the histone H2AX by SAL. A549 cells were transfected with 100 nM ATM siRNA for 24 h. The cells were analyzed directly for ATM expression (*left*) or continued to be exposed to SAL for additional 3 h for γ -H2AX detection (*right*) by Western blotting. **C.** ATR knockdown blocked SAL-induced γ -H2AX production. After 100 nM ATR siRNA transfection for 24 h, A549 cells were analyzed directly for ATR expression (*left*) or continued to be exposed to SAL for an additional 3 h for γ -H2AX detection (*right*) by Western blotting. **D.** Caffeine blocked the telomere shortening induced by SAL. A549 cells were treated with 50 μ M SAL for 3 h following the pretreatment with 2 mM caffeine for 1 h and subjected to the relative telomere length detection as in Fig. 1D. The telomere length of the control was taken as 100%. The results were expressed as mean \pm SD, n=3 (** $p < 0.01$ vs the SAL alone treated group). **E.** ATR was involved in SAL-induced telomeric length shortening. Following ATM siRNA or ATR siRNA transfection as in B and C, A549 cells were

MOL#39081

exposed to 50 μ M SAL for an additional 3 h. The relative telomere length was analyzed and expressed as in D (** $p < 0.01$ vs the SAL alone treated group).

Figure 5. TRF2 knockdown potentiates ATR activation and ATR knockdown prevents TRF2 reduction following the treatment of SAL. **A.** A549 cells were transfected with 200 nM TRF2 siRNA for 24 h and then treated with 50 μ M SAL for an additional 3 h. The cells were collected for ATR immunoprecipitation and *in vitro* ATR activity assays. Representative images of the phospho-p53 substrate detected by Western blotting were shown. Amount of phospho-p53 was semi-quantitated (*up*). **B.** After 24 h transfection with 100 nM ATR siRNA, A549 cells were treated with 50 μ M SAL for an additional 3 h and then subjected to immunofluorescence microscopy for TRF2 protein (*green, left*). The nuclei were stained with DAPI (*blue*), *bar*=4 μ m. Fluorescence of TRF2 protein was semi-quantitated by Photoshop 7.0 (*right*)
