GLP-1 = glucagon-like peptide-1

ABSTRACT

Parathyroid hormone (PTH) and parathyroid hormone-related peptide (PTHrP) bind and activate the PTH/PTHrP receptor (PTH-1R). However, while the related receptor PTH-2R responds potently to PTH, it is not activated by PTHrP. It is known that two hormone sites are responsible for these different potencies. Firstly, the absence of efficacy for PTHrP at PTH-2R is due to the presence of His-5 in PTHrP (Ile-5 in PTH) which interacts with the receptor's juxta-membrane (J) domain. Secondly, PTHrP has lower affinity than PTH for PTH-2R due to the presence of Phe-23 (Trp-23 in PTH) which interacts with the receptor's N-terminal extracellular (N) domain. We used these different receptor subtype properties to demonstrate that residue 41 in PTH-1R, when either the native Leu or substituted by Ile or Met, can accommodate either Phe or Trp at position 23 of the ligand. However, when Leu-41 is substituted by a smaller side chain, either Ala or Val (its equivalent residue in PTH-2R), the receptor becomes highly selective for those peptide ligands with Trp-23. Hence, despite the conservative nature of the substitutions found in the native ligands (Phe for Trp) and receptors (Leu for Val), they nevertheless enable a significant degree of selectivity to be achieved. Analysis of this functionally important ligand-receptor contact, within the context of the recent X-ray structure of the peptide-bound PTH-1R N domain, reveals the nature of the selectivity filter and how it is by-passed in PTH-1R.

Parathyroid hormone (PTH) and parathyroid hormone-related peptide (PTHrP) mediate many of their physiological effects via the same receptor, PTH-1R (Lanske et al., 1996). Although PTH has 84 residues and PTHrP is 141 residues in length, the biological effects they mediate via PTH-1R can be replicated by synthetic peptides equivalent to the first 34 amino acids of each peptide (e.g. Segre et al., 1979). These shorter analogues bind and activate PTH-1R in an analogous manner to the "two site model" seen at other related Family B G protein-coupled receptors (GPCRs) (Bergwitz et al., 1996; Castro et al., 2005; Lopez de Maturana et al., 2003). In this model, the ligand's C-terminal region interacts with the receptor's N-terminal extracellular (N) domain to generate affinity. This first interaction positions the N-terminal region of the peptide such that it activates the receptor via a second interaction with the receptor's juxta-membrane (J) "core" domain, comprising the transmembrane helices and connecting loops. The nature of the first interaction has been investigated via a number of mutagenic and cross-linking studies (Gensure et al., 2001; Mannstadt et al., 1998; Pham and Sexton, 2004) and more recently has been the focus of several structural studies that defined the structures of the peptide-bound N-domains of the receptors for corticotrophin-releasing factor (CRF), pituitary adenylyl cyclase-activating polypeptide (PACAP), glucose-dependent insulinotropic peptide (GIP), glucagon-like peptide-1 (GLP-1) and, very recently, PTH itself (Grace et al., 2004; Grace et al., 2007; Parthier et al., 2007; Sun et al., 2007; Runge et al., 2008; Pioszak & Xu, 2008).

In addition to its actions at PTH-1R, PTH is also a potent agonist at PTH-2R, a related receptor with approximately 50% sequence identity to PTH-1R (Usdin et al., 1995). However, despite the high potency of PTH, PTHrP binds to PTH-2R with more than 100-fold lower affinity and, furthermore, has virtually no biological efficacy. Hence, PTH acts as a potent agonist at both

receptors while PTHrP acts as a high-affinity agonist at PTH-1R while having relatively low affinity and almost no detectable efficacy at the PTH2R.

Despite sharing only 11 of their first 34 residues, an elegant study by Gardella *et al.* (1996) determined that the components of the hormones responsible for their different properties at PTH-2R are located at only two sites (Gardella et al., 1996). Firstly, Gardella *et al.* demonstrated that His-5* (ligand residues will be distinguished from receptor residues by an asterisk following the residue number) in PTHrP is the residue responsible for its absence of biological efficacy and that, when substituted by Ile (the equivalent residue in PTH), its biological activity is restored. According to the two site model for Family B GPCR peptide-ligand interactions, it would be expected that the interaction site for residue 5* in PTH and PTHrP is within the J domain and, indeed, two reciprocal studies have demonstrated this to be the case (Bergwitz et al., 1997; Turner et al., 1998). The second site demonstrated by Gardella *et al.* as being responsible for PTHrP's impaired response at PTH-2R is residue 23* which is Phe in PTHrP but Trp in PTH. Rather than influencing peptide efficacy as for residue 5, the presence of Phe at residue 23* reduces the peptide's affinity at PTH-2R by approximately 70-fold relative to the equivalent peptide with Trp-23*, despite the relatively similar nature of these two aromatic amino acid side chains. The two site model for peptide-ligand interaction would predict that residue 23* interacts with the receptor's N-domain and, once again, this has been demonstrated (Dean et al., 2006; Gensure et al., 2001; Mannstadt et al., 1998; Pioszak & Xu, 2008).

Taken together, the information from the studies reviewed above suggests that PTH-2R contains a selectivity filter within its N-domain which selects against peptide ligands containing Phe at position 23* but not against those containing Trp; we will refer to this as the "Trp23/Phe23 selectivity filter". In order to demonstrate this, we hypothesised that this selectivity filter could be

moved from PTH-2R into PTH-1R with the result of increasing PTH-1R's sensitivity to the nature

of the residue at position 23* of the ligand. Starting with a chimeric receptor to demonstrate the

proof of principle, our ultimate objective was to identify a specific residue in the N-domain that

confers the Trp23/Phe23 selectivity. The very recent publication of the X-ray structure of PTH

bound to the N-domain of PTH-1R allowed us to interpret our data in this structural context and to

explain the nature of the peptide selectivity at PTH receptors.

MATERIALS AND METHODS

Constructs. The full-length cDNA of human PTH-1R and PTH-2R (gift from GlaxoSmithKline)

were individually ligated into the multiple cloning site of pcDNA3 (Invitrogen, Groningen, The

Netherlands) using the restriction sites for *Bam*HI and *Not*I (for PTH-1R) and *Hind*III and *Xho*I

(for PTH-2R). Two cross-linking studies have determined that a benzoylphenylalanine substituted

at position 23* of PTHrP can be covalently cross-linked to the distal region of the N-domain, more

specifically to either residues 23-40 in rat PTH-1R or 33-63 in human PTH-1R (Gensure et al.,

2001; Mannstadt et al., 1998). Hence, a receptor chimera PTH1R-NT2, encoding a receptor with

residues 1-43 from PTH-2R and residues 44-593 of PTH-1R, was constructed by introducing a

unique *Afl*II restriction site into both the PTH-1R and PTH-2R cDNA at codons 42/43 using

QuikChange site-directed mutagenesis (Stratagene, Amsterdam Zuidoost, Netherlands). As a

result, His-42 and Arg-43 in PTH-1R were mutated to Leu and Lys respectively, the corresponding

residues from PTH-2R. These two pcDNA3-based constructs were then cleaved with *Afl*II, within

the cDNA, and also with *Xba*I, which cuts in the 3' polylinker region. The appropriate *Afl*II-*Xba*I

DNA fragments were gel-purified and ligated to yield the PTH1R-NT2 chimera cDNA. All

enzymes were purchased from New England Biolabs (Hitchin, UK). All other mutated receptors

were generated using QuikChange site-directed mutagenesis and confirmed by DNA sequencing. These various pcDNA3 constructs were used to express the wild type, PTH1R-NT2 chimera and mutant PTH receptors in Human Embryonic Kidney (HEK)-293 cells.

Cell culture. The HEK-293 cells were cultured in Dulbecco's Modified Eagle's Medium (DMEM, from Sigma, Poole, UK) supplemented with 10% foetal calf serum (BioWhittaker, Wokingham, UK) and containing 2 mM L-glutamine, 100 U/ml penicillin and 100 µg/ml streptomycin (Gibco, Paisley, UK). Cells were transfected with pcDNA3 containing the cDNA encoding the receptors, using the SuperFect® Transfection Reagent (Qiagen Ltd., Crawley, UK.) and stable clones were selected with geneticin/G418 antibiotic (Gibco, Paisley, UK) as follows. Cells were seeded into a 25 cm^2 flask containing 10 ml of media and transfected when they reached 50-80% confluence. To do this, 20 µl of SuperFect was mixed with a DNA solution consisting of 5 µg plasmid DNA in 150 µl DMEM. The DNA was incubated with the reagent for 10 min at room temperature after which 1 ml of media was then added and mixed gently. The cells were washed once with sterile PBS (137 mM NaCl, 10 mM Phosphate, 2.7 mM KCl, pH 7.4) before the transfection mixture was added and incubated for 3 h at 37 ^{o}C. The cells were then washed 3 times with PBS before the addition of fresh media. Three days later, the supernatant was removed and the cells were washed with PBS before fresh media was added. Selection of transfected cells was achieved by addition of 800 µg ml^{-1} G418. The media, containing G148, was replaced every 3 days until individual colonies were clearly visible. Approximately 10-20 individual colonies were detached from the flask using trypsin, seeded in a fresh plate and grown to confluence.

Peptides. PTH(1-34) and Tyr36-PTHrP(1-36) (called PTHrP(1-36) throughout the paper) were from Bachem (Saffron Walden, UK). Phe23-PTH(1-34) and Trp23,Tyr36-PTHrP(1-36) (called

Trp23-PTHrP(1-36) throughout the paper) were custom synthesised by Cambridge Research Biochemcials (Cambridge, UK) by solid phase synthesis on an Advanced ChemTech peptide synthesiser. Following HPLC purification and analysis, alongside MaldiTof mass spectrometry, 10mg of >95% pure peptide was supplied. The radioligand ^{125}I-[Nle^{8,21},Tyr^{34}] rPTH(1-34)NH$_2$ (called ^{125}I-rPTH(1-34) throughout the paper) was from Perkin Elmer (Boston, MA, USA).

Ligand binding to whole cells. Radioligand binding was carried out using cells grown in 24-well plates (adapted from Gardella et al., 1996). Each well contained a final volume of 300 µl and contained 50 pM (~60,000 cpm) ^{125}I-rPTH(1-34) and various concentrations of an unlabelled competitor ligand, all diluted in whole-cell binding buffer (50 mM Tris-HCl pH 7.7, 100 mM NaCl, 5 mM KCl, 2 mM CaCl$_2$, 5% heat-inactivated horse serum, 0.5% heat-inactivated foetal bovine serum). Binding assays were incubated at room temperature for 2 h before being washed three times with 0.5 ml whole-cell binding buffer. The cells were then lysed by addition of 0.5 ml of 5 M NaOH, and the lysate was measured for radioactivity in a gamma counter (RiaStar 5405 counter; Packard, Pangbourne, England). Total radioligand bound was <10% and non-specific binding was ~1% of total counts added. PTH-2R could only be detected in whole cell binding experiments.

Ligand binding to membranes. The method was adapted from Hoare & Usdin (1999). HEK-293 cells, cultured to confluence on five 160-cm^2 Petri dishes (pre-coated with poly-D-lysine), were washed with PBS, followed by the addition of 15 ml of ice-cold sterile double distilled water to induce cell lysis. Following 5 min incubation on ice, the ruptured cells were thoroughly washed with ice-cold PBS before being scraped from the plates and pelleted by centrifugation in a bench-top centrifuge (13,000 *g* for 30 min). The crude membrane pellet was resuspended in 1 ml membrane binding solution (MBS; 20 mM HEPES pH 7.5, 100 mM NaCl$_2$, 1 mM EDTA, 3 mM

MgSO$_4$, 50 mg L^{-1} bacitracin) and forced through a 23G needle after which 0.1 ml aliquots were snap-frozen in N$_2$(l) and stored at -70°C. Membranes were slowly thawed on ice before diluting to a concentration that gave total radioligand binding of <10% of the total counts added. In a reaction volume of 200 µl, 75 pM (~60,000 cpm),^{125}I-rPTH(1-34), various concentrations of an unlabelled competitor ligand and HEK-293 membranes expressing the receptor of interest were combined, all diluted in MBS supplemented with 0.3% non-fat milk powder (NFM). Assays were carried out in polypropylene v-bottomed 96-well plates (Nunc, Naperville, IL, USA) for 1 h. MultiScreen 96-well Filtration Plates (polyvinylidene fluoride filters, 0.45 µm pore size, Millipore, Bedford, MA, USA) were pre-soaked in a 1% NFM/PBS solution for 30 min. After the incubation, membrane-associated radioligand was harvested by transferring the assay mixture to the filtration plate housed in a vacuum manifold. The wells of the assay plate were washed with 0.2 ml MBS, which was transferred to the filtration plate. The wells were then washed three times with 0.2 ml MBS before harvesting the filter discs. Filter-bound radioactivity was measured in a gamma counter.

Data analysis. For each individual competition binding experiment, counts were normalised to the maximal specific binding within each data set. IC$_{50}$ values were calculated with a single site binding model fitted using non-linear regression with the aid of GraphPad PRISM 3.0 software (San Diego, CA, USA). Values in the tables represent the mean with S.E.M. calculated from the individual pIC$_{50}$ values (-Log IC$_{50}$) from at least three independent experiments. Binding curves in the figures represent pooled data from three independent experiments where each point is the mean of the normalised values with inter-experimental standard error of the mean displayed as error bars.

Molecular modelling. The X-ray structure of the PTH-1R N-domain with bound PTH (Pioszak

& Xu, 2008; Protein Data Bank code 3C4M) was published during the writing of this manuscript.

In order to use this new information to interpret the mutagenesis data described in this paper, *in*

silico mutagenesis of this X-ray structure was carried out using the "Mutate Monomers" tool

within the "Biopolymer" module of SYBYL v6.3 (Tripos Associates). The structure and nine

models accounted for all combinations of the receptor residue 41 as Leu, Val, Ile, Met or Ala with

the PTH peptide residue 23* as Trp or Phe. The *in silico* mutagenesis of Trp-23* to Phe resulted in

a conformation in which the benzoyl ring lay in the same plane as the original indole ring of Trp-

23*. All allowed side chain rotamers of residue 41 were then explored by adjusting the χ dihedral

angles within the ranges permitted for each residue type when located in the centre of an alpha-

helix (Penel & Doig, 2001). *Gauche(+)* refers to $\chi \approx -60°$, *trans* refers to $\chi \approx 180°$ and *gauche(-)*

refers to $\chi \approx +60°$, where χ1 was measured from the main chain nitrogen atom to γ of Leu, γ1 of Ile

and γ2 of Val, while χ2 was measured from the Cα atom to δ of Ile and δ1 of Leu. Rotamer

combinations that resulted in serious steric interference with other parts of the model were rejected

while those that formed stabilising contacts with the ligand were prioritised. Where no side chain

to side chain interaction between residue 41 and 23* could be obtained through altering the

rotamer of residue 41, modest adjustment of the rotamer of residue 23* was explored within ± 15°

of the χ1 and χ2 values found in the crystal structure. Once the particular side chains

conformations for each mutant/ligand combination had been selected, each resultant model was

subjected to energy minimisation (2000 steps of conjugate gradients using the Tripos force-field).

Models were further analysed visually using SYBYL 6.3 in order to measure atom-atom distances,

dihedral angles and to analyse the potential mechanism of the Trp23/Phe23 selectivity.

RESULTS

Figure 1A shows the sequence of PTH(1-34) and PTHrP(1-36) with position 23* highlighted in bold. The affinities of these peptides at PTH-1R and PTH-2R, expressed in whole HEK-293 cells, were estimated using competition binding assays (Figure 2, A & B). At PTH-1R, the peptides displayed a less than 6-fold difference in IC_{50} while at PTH-2R the difference was greater than 200-fold. Two additional peptides, Phe23-PTH(1-34) and Trp23-PTHrP(1-36), were used in this study by substituting position 23* of PTH(1-34) and PTHrP(1-36) respectively. The effect of these substitutions, in either peptide, was to reduce the 214-fold selectivity at PTH-2R (Figure 2B) to less than 10-fold (Figure 2, C & D).

In order to locate the site in PTH-2R responsible for the improved affinity of the peptide ligands with Trp-23* over those with Phe-23*, a chimeric receptor, PTH1R-NT2, was created with residues 1-43 from PTH-2R and residues 44-593 of PTH-1R (Figure 1B). PTH1R-NT2 and PTH-1R were expressed in HEK-293 cells from which membrane preparations were analysed using competition binding assays. The chimeric receptor had a 277-fold selectivity for PTH(1-34) over PTHrP(1-36) compared with only 16-fold at PTH-1R (Table 1; Figure 3). Furthermore, compared with PTH-1R, the PTH1R-NT2 chimera displayed a greater selectivity of Phe23-PTH(1-34) relative to PTH(1-34) (108-fold compared with 11-fold) and also for PTHrP(1-36) relative to Trp23-PTHrP(1-36) (124-fold compared with 7-fold) (Table 1). The data demonstrated that the selectivity filter in PTH-2R had been moved to PTH-1R and that, given that the first 23 residues of the receptors are signal peptides, it lies within the first 21 residues of the mature receptor. No significant differences were observed in the activation properties of PTH1R-NT2 relative to PTH-1R, as measured using concentration-response curves to measure agonist-induced cAMP accumulation (data not shown). This was expected since large affinity changes at PTH-1R are

known to result in only very modest potency changes (Gardella et al., 1996), possibly due to a

large receptor reserve, thereby making functional assays of limited use relative to binding assays in

this particular context.

The region of PTH-1R and PTH-2R made up of residues 23-43 differs at only 12 of the 21

sites. In order to identify the specific residue or residues responsible for the Trp23/Phe23

selectivity in the chimera, six site-directed double mutants of PTH-1R were prepared where pairs

of residues were replaced by their equivalents in PTH-2R. The double mutants were expressed in

HEK-293 cells and, as before, membrane preparations were analysed using competition binding

assays (Table 2). Five of the double mutants displayed a selectivity between PTH(1-34) and

PTHrP(1-36) of only 13-45-fold, compared to the 16-fold difference observed with PTH-1R.

However, one double mutant, FL39/41VV, displayed a selectivity of >500-fold. Further single

mutations at these two sites demonstrated that the increased selectivity was not due to the F39V

mutation (27-fold) but rather to the L41V substitution (>900-fold) (Table 2).

To further understand the nature of the PTH/PTHrP selectivity conferred by the Leu to Val

change at residue 41, three additional mutations were made at this site in PTH-1R to create L41A,

L41I and L41M. The Leu-41 mutants were expressed in HEK-293 cells and, as before, membrane

preparations were analysed using competition binding assays using four unlabelled peptides (Table

3). Despite the conservative nature of the substitutions introduced at Leu-41, two distinct receptor

phenotypes were observed. The first phenotype was represented by L41I and L41M which

resembled wild type PTH-1R with modest PTH/PTHrP and Trp23/Phe23 selectivity. The second

phenotype was represented by L41V and L41A which displayed a much greater PTH/PTHrP and

Trp23/Phe23 selectivity which closely resembled that observed for the chimeric PTH1R-NT2 and

wild type PTH2-R receptors. For example, Figure 4 displays a comparison of the binding

properties of PTH(1-34) and Phe23-PTH(1-34) at PTH-1R (Figure 4A) and three mutant receptors (Figures 4, B-D). The modest selectivity between the peptide ligands when reside 41 is Leu or Ile (Figure 4, A & C) is greatly increased when residue 41 is Val or Ala (Figure 4, B & D). Likewise, Figure 5 displays a comparison of the binding properties of PTHrP(1-36) and Trp23-PTHrP(1-36) at PTH-1R (Figure 5A) and three mutant receptors (Figures 5, B-D). Once again, the modest selectivity between the peptide ligands when reside 41 is Leu or Ile (Figure 5, A & C) is greatly increased when residue 41 is Val or Ala (Figure 5, B & D).

In silico mutagenesis of the crystal structure of PTH bound to the N-domain of PTH-1R was used to explore the mechanism of the Trp23/Phe23 selectivity filter. In the X-ray structure, the $\chi 1$ and $\chi 2$ conformation of Leu-41 is *trans, gauche(-)* rather than the more common *gauche(+), trans* rotamer which would result in a steric clash with Trp-23*. However, when Trp-23* is substituted by Phe-23*, the *gauche(+), trans* combination resulted in no such steric interference with he ligand but rather enabled a van der Waals contact with Phe-23* that had not possible with the original *trans, gauche(-)* rotamer. For Val and Ile at position 41, the beta-branch meant that only one conformation of $\chi 1$ was allowed, since a beta carbon atom at approximately $+60^{\circ}$ is disfavoured due to clashes with the main chain of the helix. Hence only the *gauche(+)* was possible for Val-41 while for Ile the highly favoured *gauche(+), trans* combination (Penel & Doig, 2001) resulted in steric clashes with Trp-23* (hence disallowed in the PTH-bound model) but nevertheless was the only rotamer that was able to form a stabilising van der Waals contact with Phe-23*. On the other hand, the *gauche(+),gauche(+)* combination allowed a van der Waals interaction with Trp-23* but could not interact with Phe-23*. The Met-41 mutants were built with equivalent rotamers to the Leu such that the sulphur atom was positioned with topological

equivalence to the particular δ of Leu-41 that contacted residue 23* (δ2 for Trp-23* and δ1 for

Phe-23*). The choice of the Ala-41 model was trivial since it adopts only one conformation.

The effect of these *in silico* mutations and energy minimisation on the local structure of the N-

domain was negligible, which was expected from the experimental data which clearly showed that

these mutations had no effect on PTH affinity, thereby demonstrating that the protein structure had

not been unduly perturbed.

DISCUSSION

In order to locate the Trp23/Phe23 selectivity filter (Gardella et al., 1996; Figure 2), we set out to

move it from PTH-2R to PTH-1R with the expectation that the modified PTH-1R would display an

increase in "Trp23/Phe23 selectivity". Previous work had demonstrated that position 23* binds to

the receptor's N-domain (Dean et al., 2006) and, moreover, can be cross-linked to either residues

23-40 in rat PTH-1R or 33-63 in human PTH-1R (Gensure et al., 2001; Mannstadt et al., 1998).

We therefore started our search by substituting the first 21 residues of the mature PTH-1R (Y23-

R43) with the equivalent residues in PTH-2R (R23-K43) (Figure 1B) to yield a chimeric receptor

called PTH1R-NT2. The chimera displayed a greatly increased Trp23/Phe23 selectivity (Figure 3;

Table 1), demonstrating that the selectivity filter had been successfully transferred and, moreover,

that it was likely to be the result of one or more of the 12 residues in this region that differ between

the two receptors.

The construction and analysis of six double mutants, followed by two further single mutations,

identified the Leu-41 to Val change as being the only substitution responsible for the increased

PTH/PTHrP selectivity (Table 2). Therefore, the data suggest that the highly conservative

substitution of Leu-41 of PTH-1R for Val is sufficient to impart the ability to select PTH/PTHrP peptides.

To further understand the nature of this selectivity, Leu-41 in PTH-1R was substituted by Ile, Met and Ala. While the Met and Ile substitutions resulted in receptors that resembled the Leu-41 wild type receptor, the smaller side chains of Val and Ala resulted in a remarkable increase in Trp23/Phe23 selectivity (Table 3; Figures 4 & 5). The data not only identified a receptor-ligand interaction site but also demonstrated that the nature of the Trp23/Phe23 selectivity filter was due to the size of the side chain of residue 41, with the smaller residues unable to optimally interact with Phe-23* of the ligand.

The past year has seen a great increase in our knowledge of how Family B GPCRs bind their ligands with the publication of several NMR and X-ray structures of ligand-receptor complexes (Grace et al., 2004; Grace et al., 2007; Parthier et al., 2007; Sun et al., 2007; Runge et al., 2008). Of particular relevance to this work is the very recent publication of the X-ray structure of PTH bound to the N-domain of PTH-1R (Pioszak & Xu, 2008) which has enabled a rigorous analysis of our data within the context of a precise structure of the ligand-receptor complex. Shape correlation statistics of the X-ray structure have demonstrated that the binding specificity of PTH to PTH-1R is largely determined by complimentary shape-matching between hormone and receptor (Pioszak & Xu, 2008). Furthermore, it is also clear from the crystal structure that Trp-23* of PTH does indeed interact closely with Leu-41 (e.g. Figure 6E), since there are two interactions of 3.5-3.7 Å between the Cδ2 atom of Leu-41 and the indole ring of Trp-23*. Moreover, this demonstrates that the mutagenesis/selectivity approach utilised in our analysis of this ligand-receptor interaction represented a highly successful strategy for identifying this precise and functionally relevant residue-residue contact.

Analysis of the X-ray structure and the nine *in silico* mutants indicated that Trp-23* on PTH was capable forming an intimate van der Waals contact (defined as a carbon-carbon distance of less than or equal to a 3.8 Å) with all of the mutated side chains at residue 41: Ile, Met, Val and Ala (Figure 6A-D). However, the smaller side chain of Phe-23* was only able to contact the larger side chains of Leu, Met and Ile but not the smaller side chains of Val and Ala (minimum distance possible was 4.7 Å or 5.4 Å respectively). The data demonstrate that the Trp23/Phe23 selectivity filter is formed by the reduction of the volume of the side chain at position 41. Interestingly, prior to the publication of the PTH-1R/PTH crystal structure, we had come to precisely the same conclusion through building and analysing a homology model of PTH bound to PTH-1R based upon the X-ray structure of the GIP/GIP receptor complex, demonstrating the usefulness of such models in the absence of an experimentally determined structure (Mann, 2007). However, the precision of the X-ray structure has enabled us to propose a more detailed mechanism for this remarkable and subtle selectivity filter.

We propose that the receptor species with Val or Ala at position 41 contain a crevice within the broader ligand binding groove that forms an intimate docking site for the side chain of Trp-23* but not for Phe-23* (Figure 6B, 6D). The lack of interaction with the smaller side chain of Phe-23* is the result of the small size of Val and Ala and the absence of a δ carbon atom. The resultant Trp23/Phe23 selectivity filter is eliminated in wild type PTH-1R by the presence of Leu-41 which has the conformational flexibility to switch between two different docking modes, each one optimal for either Trp-23* or Phe-23* (Figure 6 A). In one docking mode, Leu-41 maintains the small crevice to allow room for the side chain of Trp-23* while still forming a van der Waals contact through its δ2 methyl group via the rotamer χ1 = *trans*, χ2 = *gauche(-)* (Figure 6A, left). Nevertheless, by adopting the more favoured rotamer χ1 = *gauche(+)*, χ2 = *trans* (Penel & Doig,

16

2001), Leu-41 can partly fill the crevice and enable an intimate contact between the δ1 methyl group and the smaller side chain of Phe-23* (Figure 6A, right; *n.b.* this side chain rotamer would result in a steric clash between the δ1 methyl group and Trp-23*). Hence Leu-41 acts as a "rotamer toggle switch" enabling PTH-1R to adopt optimal docking sites for both Trp-23* and the Phe-23*.

In the case of the Ile-41 mutant, its beta-branch means that the χ1 dihedral must be *gauche(+)* in order to avoid a steric clash with the main chain alpha helix. With ligands that contain Phe-23*, a contact between the δ methyl group and the benzyl ring can only be formed via χ2 = *trans* (Figure 6C, right), in an analogous manner to Leu-41 (Figure 6A, right). However, this side chain conformation cannot accommodate Trp-23* due to steric interference and therefore the δ methyl group rotates out of the way by adopting χ2 = *gauche(+)* (Figure 6C, left). Indeed this side chain rotamer [χ1 = *gauche(+)*, χ2 = *gauche(+)*] is highly favoured for Ile in alpha-helices (Penel & Doig, 2001). Therefore, like Leu-41 in PTH-1R, Ile-41 can also adopt the optimal docking sites for both Trp-23* and Phe-23* via a rotamer toggle mechanism. In a similar manner, the δ sulphur atom on Met can mimic the position of the δ2 carbon of Leu-41 when interacting with Trp-23* via χ1 = *trans*, χ2 = *trans*, while the Leu-41 to Phe-23* interaction can be mimicked via the more favoured χ1 = *gauche(+)*, χ2 = *trans* rotamer.

In summary, by transferring the Trp23/Phe23 selectivity filter from PTH-2R to PTH-1R, we have identified a functionally relevant interaction between residue 41 of the receptor and residue 23* of the ligand which is compatible with the very recent X-ray structure of the ligand-receptor complex. Furthermore, by substituting Leu-41 of PTH-1R with a range of similar hydrophobic amino acids, we have demonstrated that the size of the aliphatic side chain at residue 41 is the determining factor in the ability of the receptor to select between peptides with a either Trp or Phe at residue 23*. Moreover, a detailed *in silico* mutagenesis analysis of the N-domain of PTH-1R

bound with PTH demonstrated that it is the conformational flexibility of the larger aliphatic side chain of Leu (as well as Ile and Met) which enables it to accommodate both Trp-23* and Phe-23* in PTH-1R via a rotamer toggle mechanism which can switch between the two optimal docking conformations. The absence of such conformational flexibility when residue 41 is Val (or Ala) results in the creation of the Trp23/Phe23 selectivity filter.

(A) Sequence alignment of PTH(1-34) and PTHrP(1-36), the peptides used in this study. Note that residue Ile-36 of PTHrP(1-36) has been substituted by Tyr. Conserved residues are highlighted with the asterisks (*) and the residues at position 23 are highlighted with a large/bold font. (B) A cartoon representation of the PTH receptors showing the aligned sequences of both PTH-1R and PTH-2R between residues 23-43. This region immediately follows the signal peptide (SP) and therefore represents the extreme N-terminal region of the mature receptors. The dotted line represents the remainder of the N-terminal domain, which typifies all Family B GPCRs, with the three solid lines representing the three disulphide bonds. The transmembrane core domain is represented by the bundle of seven cylinders.

FIGURE 2

Intact HEK-293 cells expressing either PTH-1R (A) or PTH-2R (B, C & D), were used in competition binding assays using ^{125}I-rPTH(1-34) as the tracer and one of four unlabelled peptide ligands: PTH(1-34) (*filled circles*); PTHrP(1-36) (*filled squares*); Phe23-PTH(1-34) (*open circles*); and Trp23-PTHrP(1-36) (*open squares*). The panels each represent a typical example of one of three independent experiments. Using whole cells, the mean pIC_{50} values at PTH-1R were 7.00 ± 0.10 for PTH(1-34) and 6.27 ± 0.26 for PTHrP(1-36), while at PTH-2R they were 7.20 ± 0.11 for PTH(1-34), 4.87 ± 0.04 for PTHrP(1-36), 5.34 ± 0.55 for Phe23-PTH(1-34) and 6.27 ± 0.20 for Trp23-PTHrP(1-36). The small selectivity of PTH(1-34) over PTHrP(1-36) observed at PTH-1R (A) is significantly enhanced at PTH-2R (B). This increase in peptide selectivity is determined by the nature of residue 23 which is Trp in PTH(1-34) and Phe in PTHrP(1-36) (C & D).

FIGURE 3

Membrane preparations from HEK-293 cells expressing either PTH-1R (A) or the chimera PTH1R-NT2 (B), were used in competition binding assays using ^{125}I-rPTH(1-34) as the tracer and two unlabelled peptide ligands: PTH(1-34) (*filled circles*); and PTHrP(1-36) (*filled squares*). The panels each represent pooled data from three independent experiments. The small 16-fold selectivity of PTH(1-34) over PTHrP(1-36) observed at PTH-1R (A) is significantly enhanced to 277-fold at PTH1R-NT2 (B). Full data for these and other peptides are shown in Table 1.

FIGURE 4

Membrane preparations from HEK-293 cells expressing either PTH-1R (A), L41V (B), L41I (C), or L41A (D), were used in competition binding assays using ^{125}I-rPTH(1-34) as the tracer and two unlabelled peptide ligands: PTH(1-34) (*filled circles*); and Phe23-PTH(1-34) (*open circles*). The panels each represent pooled data from three independent experiments. The small 11-fold selectivity of PTH(1-34) over Phe23-PTH(1-34) observed at PTH-1R (A) is significantly enhanced to 104-fold at L41V (B) despite there being only a 5-fold selectivity at L41I (C). Selectivity is increased to 705 fold in L421A (D). Full data for these and other peptides are shown in Table 3.

FIGURE 5

Membrane preparations from HEK-293 cells expressing either PTH-1R (A), L41V (B), L41I (C), or L41A (D), were used in competition binding assays using ^{125}I-rPTH(1-34) as the tracer and two unlabelled peptide ligands: PTHrP(1-36) (*filled squares*); and Trp23-PTHrP(1-36) (*open squares*). The panels each represent pooled data from three independent experiments. The small 7-fold selectivity of Trp23-PTHrP(1-36) over PTHrP(1-36) observed at PTH-1R (A) is significantly enhanced to 341-fold at L41V (B) despite there being only a 5-fold selectivity at L41I (C). Full data for these and other peptides are shown in Table 3.

FIGURE 6

A-D: Cartoon representations based on the co-ordinates of the PTH/PTH-1R N-domain crystal structure and seven of the nine final models derived from the *in silico* mutagenesis analysis. The nature of residue-41 is depicted in each panel with (A) Leu-41, (B) Val-41, (C) Ile-41 and (D) Ala-41 (the panels share the same arrangement as the binding data in Figures 4 and 5). The left hand of each panel shows the interaction of residue 41 with Trp-23* while the rights shows Phe-23*. The rotamers of the residue 41 side chains are shown as *g+ = gauche(+), g- = gauche(-)* and *t = trans* while certain side chain atom names are shown for clarity. To aid direct comparison between the rotamers of Leu, Ile and Val, $\chi 1$ was measured to γ of Leu, $\gamma 1$ of Ile and $\gamma 2$ of Val, while $\chi 2$ was measured to δ of Ile and $\delta 1$ of Leu. Van der Waals interactions between the receptor and ligand, as defined by a distance of <3.8 Å, are depicted with a dashed line. Leu-41 and Ile-41 are able to interact with either Trp-23* or Phe-23* by toggling between two alternative rotamers (i.e. via a "rotamer switch"). Val-41 and Ala-41 are able to interact with Trp-23* but not with Phe-23*.

E: Part of the X-ray structure of PTH (yellow ribbon) bound to the N-domain of PTH-1R (white ribbon) with the side chains of Trp-23* and Leu-41 highlighted. The nearest distance between the δ2 atom of Leu-41 and the indole ring is 3.5 Å. Superimposed upon the crystal structure are the *in silico* mutations of Leu-41 to Val and Trp-23* to Phe (both in green). While the γ2 atom of Val can interact with the indole ring of Trp-23* (3.2 Å) it cannot interact with the benzyl ring of Phe-23* (4.7 Å.).

TABLES

TABLE 1:

Binding properties of the chimeric receptor PTH1R-NT2 compared with wild type PTH-1R.

Values represent mean pIC_{50} values ± s.e. for three independent competition binding assays using membrane preparations and four different unlabelled ligands with ^{125}I-rPTH(1-34) as the tracer. The values are compared using d1, d2 or d3 which represent the fold-change in mean IC_{50} values where: **d1** compares PTHrP(1-36) relative to PTH(1-34); **d2** compares Phe23-PTH(1-34) relative to PTH(1-34); and **d3** compares PTHrP(1-36) relative to Trp23-PTHrP(1-36). **d1, d2** and **d3** values for PTH-2R from whole cell binding were, respectively 213, 72 and 25 (from Figure 2) or alternatively 134, 28 and 71 (from Gardella *et al*, 1996).

	PTH(1-34)	PTHrP(1-36)	d1	Phe23-PTH(1-34)	d2	Trp23-PTHrP(1-36)	d3
PTH-1R	8.02 ± 0.17	6.81 ± 0.29	**16**	6.99 ± 0.21	**11**	7.65 ± 0.15	**7**
PTH1R-NT2	8.45 ± 0.13	6.01 ± 0.05	**277**	6.42 ± 0.19	**108**	8.10 ± 0.25	**124**

TABLE 2:

Binding properties of mutant receptors compared with wild type PTH-1R.

Values represent mean pIC_{50} values ± s.e. for three independent competition binding assays using two unlabelled ligands with ^{125}I-rPTH(1-34) as the tracer. The values are compared using d1 which represents the fold-change in the mean IC_{50} value of PTHrP(1-36) relative to PTH(1-34).

	PTH(1-34)	PTHrP(1-36)	d1
PTH-1R	8.02 ± 0.17	6.81 ± 0.29	16
YL23/25RQ	8.47 ± 0.24	6.83 ± 0.08	44
