ABSTRACT

G protein–coupled receptor (GPR) 40 is a free fatty acid receptor mainly expressed in pancreatic β-cells activated by medium- and long-chain fatty acids and regulating insulin secretion via an increase in cytosolic free calcium ([Ca2+]). Activation of GPR40 in pancreatic β-cells may improve glycemic control in type 2 diabetes through enhancement of glucose-stimulated insulin secretion. However, the most clinically advanced GPR40 agonist—TAK-875 (fasiglifam)—was withdrawn from phase III because of its hepatotoxicity resulting from the inhibition of pivotal bile acid transporters. Here, we present a new, potent CPL207280 agonist and compare it with fasiglifam in numerous in vitro and in vivo studies. CPL207280 showed greater potency than fasiglifam in a Ca2+ influx assay with a human GPR40 protein (EC50 = 80 vs. 270 nM, respectively). At the 10 μM concentration, it showed 3.9 times greater enhancement of glucose-stimulated insulin secretion in mouse MIN6 pancreatic β-cells. In Wistar Han rats and C57BL6 mice challenged with glucose, CPL207280 stimulated 2.5 times greater insulin secretion without causing hypoglycemia at 10 mg/kg compared with fasiglifam. In three diabetic rat models, CPL207280 improved glucose tolerance and increased insulin area under the curve by 212%, 142%, and 347%, respectively. Evaluation of potential off-target activity (Safety47) and selectivity of CPL207280 (at 10 μM) did not show any significant off-target activity. We conclude that CPL207280 is a potent enhancer of glucose-stimulated insulin secretion in animal disease models with no risk of hypoglycemia at therapeutic doses. Therefore, we propose the CPL207280 compound as a compelling candidate for type 2 diabetes treatment.

SIGNIFICANCE STATEMENT

GPR40 is a well-known and promising target for diabetes. This study is the first to show the safety and effects of CPL207280, a novel GPR40/free fatty acid receptor 1 agonist, on glucose homeostasis both in vitro and in vivo in different diabetic animal models. Therefore, we propose the CPL207280 compound as a novel, glucose-lowering agent, overcoming the unmet medical needs of patients with type 2 diabetes.

Introduction

G protein–coupled receptor (GPR) 40 (or FFA1) is a free fatty acid receptor mainly expressed in pancreatic β-cells (Itoh and Hinuma, 2005; Schnell et al., 2007). It mediates signaling from free fatty acid (FFA) to modulate glucose-stimulated insulin secretion (GSIS) (Briscoe et al., 2003; Itoh et al., 2003). GPR40 emerged as an antidiabetic target and was proposed as a novel treatment modality for patients with type 2 diabetes.
diabetes (Hara et al., 2011) in whom blood glucose control by popular drugs (i.e., metformin) is insufficient. Modulation of GSIS by FFA is perceived as an adaptive mechanism in a T2D milieu. A high concentration of lipids aggravates insulin resistance while enhancing insulin secretion to match the systemic demand (Nagasumi et al., 2009). Glucose dependence of the GPR40 insulotropic activity is particularly important from the clinical perspective. Interestingly, it may allow prevention of the main adverse effect (iatrogenic hypoglycemia) of the currently popular sulfonylureas (SUs), which stimulates insulin secretion irrespective of glucose levels (Sola et al., 2015). Consequently, sulfonylureas impart a constant workload on β-cells instead of ensuring a fine-tuning of insulin secretion depending on the demand. This, in turn, leads to a Ca^{2+} overload and propels β-cell dysfunction, leading to cell death (Iwakura et al., 2000).

Impairments of β-cells function and mass decline as the T2D signs of progress are caused in part by elevated FFAs described as glucolipotoxicity (Poitout et al., 2010). Although GPR40 is a receptor for FFAs that might suggest its deleterious effects, aggregating evidence shows that GPR40 is not the gateway for glucolipotoxicity (Latour et al., 2007; Kebede et al., 2008; Lan et al., 2008; Alquier and Poitout, 2009). This fundamental feature permits GPR40 to become a promising candidate target for a novel secretagogue. Nevertheless, for successful therapy, the novel GPR40 agonist must also be safe, which means being structurally different from FFAs, to circumvent their toxicity. Moreover, to become fully developed, the drug must show much greater potency than FFAs and must not induce tachyphylaxis (Sharma and Alonso, 2014). Meeting all of these three conditions has become particularly challenging on the pathway of GPR40 synthetic agonist development. For example, fasiglitam (TAK-875; Takeda) was shown not to cause tachyphylaxis, and it demonstrated 400 times greater potency at GPR40 than the cognate ligand oleic acid (Tajijhata et al., 2011; Ito et al., 2016). It showed an anti-diabetic effect in numerous animal diabetes models by improving glucose control in both acute and chronic administration (fasting parameters) (Ito et al., 2013, 2016). More importantly, it improved glucose tolerance and hemoglobin HbA1c levels in a small phase II clinical study (n > 50) in a cohort of mixed-ethnicity subjects (Burant et al., 2012). However, in a large-population phase III study (n > 5000), it demonstrated safety alerts in 2.5% of individuals (Marcinak et al., 2017). Although its structure was profoundly different to that of FFA, it turned out to be toxic for hepatocytes in the liver (especially through bile acid inhibition) (Li et al., 2015; Wolenski et al., 2017). Ever since TAK-875 entered phase III clinical trials, we have kept it as a benchmark for comparison purposes.

We have developed CPL207280, a new agonist of GPR40, which is at least three times more potent at human GPR40 and 10 times less toxic on insulinoma cells than TAK-875, which translates into a broader therapeutic window. Here, we compare the biologic properties of CPL207280 and TAK-875, and we have found that the addition of CPL207280 improved glucose tolerance in MIN6 pancreatic β-cells as well as in healthy Wistar Han rats and diabetes rat models (GK, ZDSI, ZDF rats). Incubation of CPL207280 with the rat and mouse insulinoma (INS-1 and MIN6) cells for 48 hours did not cause significant cell viability changes, whereas TAK-875 reduced rat and mouse insulinoma cell viability at higher concentrations, indicative of a narrower safety window.

### Materials and Methods

#### Cells and Compounds

CHO cell line overexpressing human GPR40 receptor and aequorin was obtained from Perkin Elmer (EBL-632, Aequorin, USA). Mouse insulinoma (MIN6, C0018006) and rat insulinoma (INS-1) cell lines (C0018007) were obtained from AddexBio. GW1100 was obtained from Calbiochem (371830). Cells were routinely tested for possible mycoplasma contamination.

CPL207280 and TAK-875 molecules were synthesized in-house with a purity >98% as based on high-performance liquid chromatography (HPLC) area integration with UV detection at a wavelength of 254 nM (Mach, et al., 2019).

#### Aequorin Assay

CHO cells overexpressing human GPR40 receptor and aequorin were seeded in a T25 flask with a Ham’s F-12 full medium 24 hours before the experiment. Subsequently, 2.5 × 10^6 cells were collected by trypsinization with 0.25% trypsin for 3 minutes, centrifuged (200g, 5 minutes), and resuspended in a 1-ml HBSS buffer (Gibco). Free fatty acids free (FFAF) 10%-BSA (final concentration 0.015%) and Coelenterazine h (in a methanol solution, final concentration 5 μM) were diluted in an HBSS buffer, added to the cell suspension, and agitated gently for 2 hours at room temperature (RT). Next, cells were suspended with HBSS and mixed for the next hour. Then, cells were transferred into a glass cylinder with a magnetic mixer, mixed, and seeded (final density 5000 cells per well) on a 96-well plate comprising an array of investigated compounds in dilutions. The measurement of the luminescence signal was carried out continuously for 1 minute, and the resulting curves were used to calculate the area under the curve (AUC). CPL207280 activity was calculated as a percentage of ω-linolenic acid activity (used as a control) at 10 μM.

#### Cell Viability Assay

For the cell viability assay, 20 × 10^3 INS-1 or 50 × 10^3 MIN6 cells were seeded in 100 μl of RPMI 1640 or Dulbecco’s modified Eagle’s medium full media (with 0.05 μM β-mercaptoethanol) in a 96-well plate (transparent bottoms) coated with poly(lysine) (Corning). On the following day, 100 μl of the full media containing 500 μM RT-Glo (Promega) and a 2× concentrated tested compound at 5 concentrations up to 100 μM was added. After 48 hours of incubation at 37°C and 5% CO2, the luminescence was measured using the VICTOR Nivo Multimode Microplate Reader (Perkin Elmer).

#### Insulin Secretion Assay

MIN6 or INS-1E cells (50 × 10^3 per well) were seeded in a 96-well plate (transparent bottoms) coated with poly(lysine). After 72 or 48 hours, respectively, cells were washed twice with Krebs-Ringer bicarbonate HEPES buffer (KRHB) containing 5.6 mM glucose and 0.1% FFAP BSA and incubated in this buffer for 2 hours at 37°C. Before the end of starvation (15 minutes), GW1100 was added to dedicated wells with INS-1E cells to a final concentration of 10 μM. Next the medium was replaced with KRHB supplemented with 20 mM glucose and CPL207280 and TAK-875 at concentrations up to 40 μM or GW1100 at a concentration of 10 μM, and cells were incubated for 1 hour. Finally, 100 μl of supernatant was collected, centrifuged at 1500g for 5 minutes, and frozen at −80°C. On the next day, the samples were diluted in KRHB, and insulin levels were determined using a mouse or rat insulin ELISA kit (Merodia) in line with the manufacturer's instructions. Cells remaining in the well were lysed with a radioimmunoprecipitation assay (RIPA) buffer, and the total protein concentration, used for insulin concentration normalization, was measured using a BCA kit (Thermo Fisher).

#### Off-Target Analysis

The selectivity of CPL207280 against representative members of GPCR and PPAR was performed using GPCR Screening and Profiling Services by DiscoverX (Eurofins DiscoverX Corporation, Fremont, CA) in line with the service provider’s protocol.

The assays were performed at 10 μM, utilizing the Calcium No Wash PLUS (FFAR2), Path-Hunter β-Arrestin (FFAR3, FFAR5, GPR119, GPR120, GPR142), Hit Hunter cAMP assay (glucagon-like peptide-1 receptor (GLP1R), and NHR Protein Interaction (PPARα, PPARγ) functional cell-based assays. The compound activity was analyzed using the chemical and biological information system (CBIS) data analysis suite (ChemInnovation, CA).
Safety 47 assay, a panel of 47 potential off-target proteins, was performed by DiscoverX (Eurofins DiscoverX Corporation, Fremont, CA) in line with the service provider's protocol. The screening was performed at 10 μM using functional cell-based, binding, and enzymatic assays utilizing the Calcium No Wash™ assay (adenosine A2A receptor -ADORA2A, ADRA1A, arginine vasopressin receptor 1A - AVPRA, cholecystokinin A receptor -CCKAR, CHRM1, CHRM3, endothelin receptor type A -EDNRA, HH1R, HTRA2, HTRA2B), NHR Protein Interaction assay glucocorticoid receptor -GR), Nuclear Translocation assay androgen receptor -AR), Ion Channel Assay (calcium channel, voltage-dependent, L type, alpha 1c subunit -CAV1.2, gamma-amino butyric acid type A receptor -GABAAR, mGluR6, HTRA3, potassium voltage-gated channel KQT-like member 1/minimal potassium channel -KcQ17tuniku, nicotinic acetylcholine receptors -nAChR (α4β2), voltage-gated sodium channel subunit α -NAV1.5, N-methyl-D-aspartate receptor -NMDAR (1A/2B), DAT, Hit Hunter CAMP assay (HTR1B, ORPR1, OPRK1, ADR2A, ADRB1, ADRB2, CHRM2, CNR1, CNR2, DRD1, DRD2S, HTR2H, HTR1A), KINOMEscan kinase binding assays (insulin receptor -INSR, LCK, ROCK1, VEGFR2), Neurotransmitter Transporter Uptake Assay (DAT, norepinephrine transporter -NET, serotonin transporter -SERT), and a variety of enzyme inhibition assays (acetohydroxamide - AChE, COX1, COX2, monooxigenase oxide A -MAOA, PDE3A, PDE4D2).

The compound activity was analyzed using the chemical and biological information system (CBIS) data analysis suite (ChemInnovation, CA). Detailed information about each assay condition is available at the Eurofins DiscoverX Corporation website.

Animal Care. The following animals were used this study: 8- to 9-week-old male C57BL/6cdmb mice (Experimental Center of the Medical University in Białystok), 8- to 10-week-old male Wistar Han rats [Crl:WI (Han); Charles River], 10- to 12-week-old male ZDSD rats (ZDSd/Peo; Crown Bioscience), 10- to 12-week-old GK rats (GK/Moltac; Taconic), and 9-week-old ZDF and ZL rats (Vital River Laboratories Research Models and Services; Beijing, China). All animals (except ZDF rats) were maintained on a standard chow diet (recommened by the supplier) and acclimated to the experimental facility about the physical condition of the animals during the study after the measurements). The fasting blood glucose level was used for animals that had access to food for 8 hours during the day and were fasted overnight.

All animals were housed in cages on a ventilated rack. The animals were housed under a 12-hour light/dark cycle (and were allowed ad libitum access to water). During quarantine, animals were marked, weighed, and had a blood glucose measurement (adapted to venous punctures in the tail vein and the experimenter performing the measurements). The fasting blood glucose level was used for animal randomization to experimental groups (n = 7/8) in the glucose tolerance test (GTT) study.

All procedures on animals were conducted in accordance with the relevant national regulatory guidelines, and individual experiments were approved by the Local Bioethics Committee in Poland (approval number: 15/2013; 32/2016; 42/2017).

Pharmacokinetic Study. Wistar Han rats (n = 4/5) were fasted for 12 hours, and at specific times after oral or intravenous administration of CPL207280 (5% DMSO/40% PEG300/55% PBS) (0.08, 0.25, 0.5, 1, 2, 4, 7, 12, and 24 hours), each animal was bled by venipuncture, and the samples were collected into tubes containing the anticoagulant, K2EDTA. Tubes were placed on wet ice preceding processing. Next, the samples were centrifuged (1200g for 5 minutes at approximately 4°C). The plasma (CPL207280) was extracted from an aliquot of the plasma (K2EDTA plasma) in line with the protein precipitation assay. The extracted samples were injected into an ultrahigh-performance liquid chromatography (Infinity II Agilent Technologies 1290) coupled with tandem mass spectrometry (Sciex QTrap 6500). The calibration range for this assay spanned from 10.0 to 2000.0 ng/mL. The mean Cmax and Tmax values from Table 3 are read from a compound concentration plot.

Glucose Tolerance Test. Male C57BL/6cdmb mice were fasted for 12 hours and administered intravenously (tail vein) with the 10 mg/kg of CPL207280, TAK-875, or the vehicle (5% DMSO/40% PEG300/55% PBS); the glucose bolus was administered immediately after that. Just before and after 0.25, 0.5, 1, 2, 2.5, and 3 hours after administration of a compound, glucose concentration in blood was measured.

Wistar Han rats were fasted for 12 hours and then administered orally with 10 mg/kg of CPL207280, TAK-875, or the vehicle (5% DMSO/40% PEG300/55% PBS), and the first glucose bolus was administered immediately after that. The second glucose bolus was administered 6 hours later. Prior to the glucose administration and after 0.08, 0.25, 0.5, 1, 2, 3, 6.25, 6.5, 7, 8, and 9 hours, glucose concentration in blood was measured. Insulin concentration in blood was measured only during the first glucose bolus administration.

ZDSD rats were starved for 6 hours, after which they were orally administered CPL207280 at 3, 10, 30, and 100 mg/kg b.wt.; TAK-875 at 100 mg/kg; glibenclamide at 30 mg/kg; or the vehicle (0.9% NaCl). At 1 hour later, a glucose bolus was administered. Blood glucose and insulin were measured 1 and 0.5 hours prior to glucose administration, as well as during the glucose challenge for up to 4 hours. GK rats were fasted for 6 hours and next given orally 30 mg/kg CPL207280, TAK-875, or the vehicle (5% DMSO/55% PEG300/40% PBS). At 1 hour later, animals were challenged with glucose. Blood glucose and insulin were measured right before drug and glucose administration and over the course of the GTT at t = 0.08, 0.25, 0.5, 1, 2, 3, and 6 hours. Because of the high concentration of fasting blood glucose observed in ZDSD and GK rats, there was a concern about the physical condition of the animals during the study after being fasted overnight. Therefore, in line with the animal supplier’s suggestion, we decided to reduce the fasting time from 12 to 6 hours. This was sufficient for obtaining glucose level standardization and did not affect the animals’ condition or the experiment results.

ZDF rats were fasted overnight for 16 hours and orally gavaged at 5 and 15 mg/kg of CPL207280, 15 mg/kg of TAK-875, or the vehicle (0.9% NaCl), followed by an oral glucose bolus 0.5 hours after the dose. Blood samples for glucose and insulin measurement were collected from each animal right before drug administration; just before glucose loading; and after 0.25, 0.5, 1, and 2 hours after glucose administration. In all in vivo studies, animals (except ZDF rats) were intraperitoneally challenged with a glucose bolus (2 g/kg). At different time points, one or two drops of blood were directly used for a glucose measurement using an Accu-Chek Performa glucometer. For insulin measurement, blood was sampled from the jugular vein, allowed to clot for a minimum of 30 minutes at room temperature, and then centrifuged at 4°C, 10,000 rpm, for 10 minutes. The resultant serum was analyzed using a Rat Insulin ELISA kit (Merodia).

The time and administration mode of glucose during the GTT study were changed during the compound development. In the first, proof-of-concept animal studies on healthy animals, glucose was administered intravenously immediately after compound administration because of CPL207280’s good pharmacokinetic properties (Table 3). During the compound development, to allow for a comparison of CPL207280 results with other GPR40 agonists, whose pharmacokinetics are different from ours and the Tmax occurs later e.g. TAK-875 (Negoro et al., 2010), the time of glucose bolus administration. During the GTT study in ZDSD and GK diabetic rat models, we observed that insulin concentration peak occurred 0.5 hours after compound administration. After combining those findings with the data from the TAK-875 study on ZDF rats (Ito et al., 2013) in which glucose was administered orally, we decided to adapt this study to the literature data.

Statistical Analysis. Statistical analysis was performed using GraphPad Prism software (version 7). All experiments presented in this manuscript were exploratory, so the null hypothesis has not been stated. Experimental data are presented as means ± S.D. EC50 value was determined based on logarithm values using nonlinear regression (curve fit) and four-parameter variable slope equation. Statistical significance between the mean of the treated groups was compared with the mean of the control group using one-way or two-way ANOVA followed by a post
**Results**

**Characteristics of CPL207280 Activity In Vitro**

After reviewing the compound library in search of GPR40 agonists, we identified CPL207280 (Fig. 1) as the lead structure for further development. In contrast to TAK-785 and other GPR40 agonists, CPL207280, by incorporation into its structure small acyclic motifs, has significantly reduced the molecular weight and overall lipophilicity at physiologic pH = 7.4 to avoid potential liver toxicity adverse effects (Mach et al., 2019).

The activity of CPL207280 on GPR40 was characterized using a variety of biochemical and cell-based assays on cell lines that expressed GPR40. To compare the efficacy of CPL207280 and TAK-875 (the best characterized GPR40 agonist so far), we used the Ca$^{2+}$ release assay in CHO cells expressing a human GPR40. In this assay, Ca$^{2+}$ released from internal stores of endoplasmic reticulum (ER) competes with coelenterazine in a complex with aequorin, resulting in a shift of absorbance at 470 nm. The measurements were performed in the presence of a low concentration of FFAF BSA to minimize the effect of albumin binding. CPL207280 demonstrated EC$_{50}$ of 80 nM and TAK-875 of 270 nM (Fig. 2), which shows three times lesser potency of TAK-875. CPL207280 tested with the use of the Calcium No Wash$^\text{PLUS}$ Assay, Path-Hunter β-Arrestin, and NHR Protein Interaction assays did not demonstrate any activity on the related GPR receptors, i.e., GPR41 (FFA2), GPR43 (FFA3), GPR55, GPR119, GPR120, GPR142, PPAR$\alpha$, or PPAR$\gamma$; when applied at 10 μM concentration; this indicates that the activity was specific to GPR40 (Table 1).

**Potentiation of Insulin Secretion by CPL207280 in Mouse and Rat Insulinoma Cells**

A GPR40 receptor is expressed predominantly in β-cells of the pancreatic islet, and its activation improves glucose-stimulated insulin secretion (Itoh and Hinuma, 2005; Schnell et al., 2007). We studied the insulinotropic effect of CPL207280 and TAK-875 in mouse (MIN6) and rat (INS-1E) insulinoma cells. Cells were maintained for 2 hours under low-glucose (LG) (2.8 mM) conditions and next were exposed to high glucose (HG) (20 mM) for 1 hour. The addition of compounds to HG cultures increased the amount of secreted insulin both in MIN6 (Fig. 3A) and INS-1E (Fig. 3B) cells. A significant effect for TAK-875 was observed only at the highest concentration (40 μM), whereas for CPL207280, a similar effect was present at all tested concentrations, suggesting greater potency of the latter (Fig. 3A). The effect for CPL207280 was dose-independent. To study whether CPL207280s effect is mediated via the GPR40 receptor, we treated the INS-1E cells with a selective antagonist of the GPR40 receptor, GW1100. In the presence of GW1100, the glucose-stimulated insulin secretion by CPL207280 was abolished (Fig. 3B). The fact that GW1100 blocked this action confirmed that the observed GSIS effect of CPL207280 is mediated via GPR40.

**CPL207280 Treatment Does Not Induce Cytotoxicity In Vitro**

Calcium overload in pancreatic β-cells compromises their viability through a mechanism known as excitotoxicity (Mädler et al., 2005). This phenomenon is ascribed to SUs as the adverse effect contributing to its secondary failure. Sulfonylureas hold the plasma membrane in the depolarized state by inhibition of K$_{\text{ATP}}$. This in turn causes a voltage-gated calcium channel–dependent influx and excess of Ca$^{2+}$ in the cytosol. The activation of GPR40 also leads to rises in [Ca$^{2+}$]$_i$ and hence may aggravate excitotoxicity. Furthermore, GPR40 was found to activate voltage-gated calcium channels, which inevitably contributes to elevated intracellular Ca$^{2+}$ levels (Fujiwara et al., 2005). To address potential excitotoxicity, we tested whether long-term treatment with CPL207280 may reduce the viability of β-cells under stimulatory conditions. INS-1 and MIN6 cells were incubated in media supplemented with 11.2 mM glucose with the tested agonists at various concentrations for 48 hours. Next, cell viability was measured with an RT-Glo assay, which is based on luciferase activity in the presence of intact cellular metabolism. CPL207280 did not affect the viability of MIN6 cells at concentrations up to 100 μM. By contrast, TAK-875 reduced...
cell viability by 63% at higher concentrations (Fig. 4A). A considerably stronger effect occurs in INS-1 cells, for which reduction of cell viability by 25% was observed after treatment with CPL207280 only at 100 μM. In case of TAK-875, 37% less viability was detected at 5 μM with up to 100% of dead cells at 10 μM (Fig. 4B).

Safety-related drug failures remain a major challenge during drug development. Off-target interactions are often the cause of adverse drug reactions (ADRs) in animal models or clinical studies. That is why careful characterization and identification of drug candidates’ secondary pharmacology profiles early in the drug discovery process might help reduce the incidence of ADRs (Bowes et al., 2012). To identify undesirable off-target activities that could impair the development of CPL207280 (as was the case with TAK-875), we performed a screening of 47 most common off-targets (Safety47 Panel, Eurofins).

Safety47 Panel consists of assays designed to study the activity of several GPCR, transporters, ion channels, nuclear receptors, kinases, and nonkinase enzymes. The experiment was performed at 10 μM, the concentration 125 times higher than EC50 to the intended therapeutic target. The results of each test in the panel (both agonist and antagonist mode) are considered negative if the activation or inhibition of a given pathway does not exceed 70% of the control.

The obtained results, summarized in Table 2, showed that CPL207280 neither inhibits nor activates any of the studied pathways. Therefore CPL207280 shall be regarded as a safe compound in terms of biomarkers tested in Safety47 Panel.

### Pharmacokinetic Study

The PK profile of CPL207280 was studied in Wistar Han rats (Fig. 5; Table 3) after administration orally and intravenously at a dose of 3 mg/kg. Compound CPL207280 demonstrated high plasma clearance, resulting in plasma half-life of 1.4 hours. This could be advantageous compared with TAK-875, which, when administered at high doses, induced accumulation of total bile acids in circulation in rats and dogs and caused liver injury accompanied by elevation of alanine aminotransferase (ALT) and bilirubin (Wolenski et al., 2017). Additionally, oral administration of CPL207280 exhibited rapid absorption, high Cmax and high plasma exposure with high bioavailability (63%) (Table 3).

### Efficacy of CPL207280 in Healthy Rodents

The first proof-of-concept study consisted of a GTT performed in young C57BL6/cmdb male mice. To ensure maximal drug exposure, mice were administered intravenously (tail vein) either the respective compound (10 mg/kg) or the vehicle. Glucose was administered immediately after the injection. Next, blood glucose was measured for up to 120 minutes with a standard glucometer. Both compounds reduced glucose levels in a similar, effective fashion and reduced the AUC 2 times compared with the vehicle (Fig. 6). No adverse effects, including changes in the animals’ behavior, were observed during the study.

We further tested whether a single dose of CPL207280 can improve a postprandial glucose range after consecutive glucose

*Fig. 3.* The effect of CPL207280 on GSIS in vitro. The dose-response relationship of CPL207280 and TAK-875 on insulin secretion in MIN6 cells (A) and effect of GW1100 on CPL207280 potentiation of insulin secretion in INS-1E cells (B) were evaluated after 1-hour incubation; Control (CTR)-untreated cells at 20 mM glucose. Data are presented as mean fold changes ± S.D. of control (untreated cells at 20 mM glucose) from three independent experiments performed in two technical replicates each (A) and four independent experiments performed in two technical replicates each (B). Data were analyzed using one-way ANOVA test (Dunnett’s post hoc). *P* < 0.05; **P** < 0.01. LG- low glucose (2.8 mM); HG - high glucose (20 mM).
challenges 6 hours apart. CPL207280 displayed excellent pharmacokinetic properties. The compound after a single 3-mg/kg dose in rats displayed excellent oral bioavailability (%F = 63), a total plasma Cmax of 1.7
\( \text{mg/ml} \), but also a shorter half-life (1.4 hours versus 4.1 hours for the TAK-875 compound) (Negoro et al., 2010) (Table 3). To be sure that the concentration of the CPL207280 in the blood allows it to be effective in glucose lowering 6 hours after administration (during the second GTT), a 10-mg/kg dose was selected for this study. CPL207280 administration in fasted state did not have any effect on glucose levels prior to the glucose tolerance test (30 minutes after CPL207280 administration). No adverse effects, including changes in the animal's behavior, were observed during the study. Interestingly, both CPL207280 and TAK-875 reduced glucose levels significantly after the first, but also after the second, glucose challenge, 6 hours post–drug administration (Fig. 7A). However, only CPL207280 demonstrated a substantial and statistically significant reduction of glucose AUC: by 50% in the first (Fig. 7D) and 25% in the second GTT (Fig. 7E). This effect is likely to have resulted from its greater capacity to enhance GSIS, as CPL207280 evoked a substantial elevation of insulin levels in the first hour compared with TAK-875 (Fig. 7B). In total, CPL207280 increased the insulin level (presented as AUC) 13.6 times, whereas TAK-875 augmented AUC 5.5 times (Fig. 7F). The increase of plasma insulin levels was most evident 15 and 30 minutes after glucose administration. The therapeutic effect durability suggests that administration of CPL207280 once daily may improve postprandial hyperglycemia in subjects with diabetes throughout the day.

**Fig. 4.** Cytotoxicity of CPL207280 in insulinoma cells. The viability of MIN6 (A) and INS-1 (B) cells after 48-hour incubation with CPL207280 and TAK-875 at concentrations up to 100 \( \mu \text{M} \) was evaluated using a luminescence assay. Control cells were treated with 0.5% DMSO, a solvent. Data are presented as mean fold changes of control cells ± S.D. from three independent experiments performed in two technical replicates each. Data were analyzed using a two-way ANOVA test (Sidak post hoc). **\( P < 0.05; \) ****\( P < 0.0001 \) vs. control.

**CPL207280 Stimulates Insulin Secretion and Reduces Postprandial Glucose Levels in Diabetic Rats**

**Zucker Diabetic Sprague-Dawley Rat Model.** To assess the capacity of CPL207280 to improve glycemia in diabetic rodent models and compare it with TAK-875, the reference compound, as well as with glibenclamide, a sulfonylurea available on the market, a dose-response study was performed in a ZDSD rat. A ZDSD rat is a new T2D animal model that was developed to display polygenic obesity and diabetes with an intact leptin pathway (Peterson et al., 2015). Rats aged 12 weeks were fasted for 6 hours, and next the compounds or the vehicle was administered orally at doses 3, 10, 30, and 100 mg/kg b.wt. The 100-mg/kg dose was also chosen to study the potential risk of hypoglycemia. A glucose bolus was administered 1 hour later. Blood glucose was measured 1 hour and 0.5 hours prior to the glucose bolus administration, as well as during a glucose challenge for up to 4 hours. No adverse effects, including changes in the animals’ behavior, were observed during the study. No hypoglycemia events were observed, even for the highest dose of 100 mg/kg. CPL207280 improved glucose tolerance and reduced glucose AUC already at the lowest dose by 38%, and the effect was dose-independent (no significant differences between doses), as the AUC values for all doses were reduced to a similar degree (Fig. 8, A and B). The improvement in glucose excursions was a result of an increase of GSIS by 207% (AUC) (Fig. 8D). This effect was also dose-independent (no significant differences between doses were observed), and the second highest observable effect was recorded at the lowest dose. The results suggest that EC50 for CPL207280 in vivo is less than 3 mg/kg. In contrast to healthy animals, the glucose-lowering and insulin augmenting effect was observed before stimulation with a glucose bolus. The increase of plasma insulin levels was most evident at 0.5 hours after the compound administration (before the glucose bolus); however, after the glucose load, it is still at a very high level (significantly different from the vehicle) even 3 hours after the glucose load (for dose 30 and 100 mg/kg).
The effects of insulin secretion before the glucose load was expected, as in fasted ZDSD rats, hyperglycemia is still present and permits action of CPL207280 to further propel insulin secretion. Surprisingly, although TAK-875 and glibenclamide increased GSIS by 211% and 251%, respectively, they failed to improve glucose tolerance or reduce glucose AUC.

Goto-Kakizaki Rat Model. A GK rat is a lean model for T2D that accumulates mutations in the pancreas that cause both β-cell mass cell death and impairment of their function. In turn, these events cause insufficient insulin secretion and evoke glucose intolerance, leading to diabetes (Al-Awar et al., 2016). Because of the lower potential of insulin secretion expected in this model, although the 3-mg/kg dose was already effective in the ZDSD rats study, in this study we decided to choose one of the higher doses to get the maximum possible antidiabetic effect.

To study the effectiveness of CPL207280, 14-week-old GK rats were fasted for 6 hours and then were orally administered 30 mg/kg of the test compounds or the vehicle. At 1 hour later, the animals were challenged with glucose. Blood samples were probed for glucose and insulin measurements. No adverse effects, including changes in the animals' behavior, were observed during the study. Rats treated with CPL207280 showed considerably improved glucose tolerance as compared with vehicle-treated rats (Fig. 9A). The effect emerged at 5 minutes after administration and remained significant for up to 6 hours. CPL207280 lowered the glucose AUC by 30% (Fig. 9B). Furthermore, rats treated with CPL207280 demonstrated elevated levels of insulin 1 hour after drug administration and after 1 and 2 hours from the glucose challenge (Fig. 9C), but due to impairment in β-cell function in GK rats, this effect is not as strong (and significant) as in other rat models. In contrast, TAK-875 given at the same dose demonstrated a moderate effect, which did not reach statistical significance (Fig. 9, A and C). The insulin AUC (counted from the baseline concentration at $t = -1$ hour) increased by 143% for CPL207280 compared with the control AUC (Fig. 9D). TAK-875 demonstrated a weaker improvement of an insulin AUC and thus lower glucose-normalizing capacity in GK rats.

Zucker Diabetic Fatty Rat Model. A ZDF rat is a popular model for T2D that develops obesity and insulin resistance at a young age. Hyperglycemia, progressively developing with age, is associated with impaired pancreatic β-cell function, loss of pancreatic β-cell mass, and decreased responsiveness of liver and extrahepatic tissues to the actions of insulin and glucose (Pal et al., 2016). To study the effectiveness of CPL207280 and TAK-875 in this model, 16-hour fasting ZDF rats were administered the tested compounds orally at 5 and 15 mg/kg first and then glucose 30 minutes after a primary dosing. Blood glucose and insulin were determined in each animal up to 2 hours after glucose administration. No adverse effects, including changes in the behavior of the animals, were observed during the study. Serum glucose AUC was decreased significantly in all treatment groups (Fig. 10B) by 81%, 77%, and 70% for CPL207280 at 5 and 15 mg/kg or TAK-875, respectively. The glucose tolerance in the CPL207280-treated group was even better than that in the normal ZL rats used as a control (Fig. 10, A and B). Serum insulin AUC was enhanced significantly.
and was dose-dependent in the CPL207280-treated group (Fig. 10, C and D). The amount of insulin secreted after CPL207280 administration was elevated significantly 15 minutes after glucose load; therefore, despite the maximum insulin concentration observed 30 minutes after glucose load (Fig. 10C), the blood glucose level decreased already after 15 minutes (Fig. 10A).

Discussion

GPR40 (or FFA1) belongs to the GPCRs family and is highly expressed in β-pancreas cells. Activation of GPR40 by medium- and long-chain FFAs or synthetic compounds has been reported to enhance insulin secretion in a glucose-dependent manner and is considered to have potential as a novel target for the treatment of T2D (Mancini and Poitout, 2015). The present results showed that CPL207280 increased Ca^{2+} in CHO cells expressing human GPR40 with a higher potency than TAK-875 (the reference compound; Fig. 2) and had no impact on cells expressing related receptors: GPR41 (FFA2), GPR43 (FFA3), GPR55, GPR119, GPR120, GPR142 (Table 1). Despite activation of GPR40/FFA1 by some thiazolidinediones acting as PPARγ agonists (Kotarsky et al., 2003), CPL207280 was found to not affect PPARα or PPARγ in a nuclear receptor reporter activation assay (Table 1). Collectively, these data demonstrate that CPL207280 is a potent and selective GPR40/FFA1 agonist with a mechanism distinct from those of other clinically available oral insulino- tropic drugs, including SUs and dipeptidyl peptidase-4 inhibitors (Winzell and Ahren, 2007).

Long-chain FFAs, natural ligands for GPR40, acutely enhance insulin secretion, and chronic exposure to FFAs causes toxicity, such as death or dysfunction of β-cells (Sharma and Alonso, 2014). Therefore, GPR40/FFA1 has been considered as a potential mediator of lipotoxicity (Steneberg et al., 2005), but a number of experimental observations do not support the central role of GPR40/FFA1 in lipotoxicity (Latour et al., 2007; Kebede et al., 2008; Lan et al., 2008; Alquier and Poitout, 2009). In the present study, we did not observe any signs of toxicity in insulinoma cells treated for 48 hours, in contrast to TAK-875, which reduced viability of rat and mouse insulinoma cells at higher concentrations, which suggests a narrower window of safety (Fig. 4). These data are in contrast to the previously presented results (Tsujihata et al., 2011) that showed no evidence of β-cell dysfunction in vitro after the prolonged exposure to TAK-875. Authors showed that TAK-875 did not affect caspase 3/7 activity after prolonged 72-hour incubation. Nonetheless, it must be emphasized that although caspase 3/7 activity is widely accepted as a reliable indicator for cell apoptosis, it may not reflect other types of death potentially mediated by TAK-875, e.g., necrosis. Additionally, 1% BSA in culture medium was used in the TAK-875 study. In this paper, we presented data from experiments in which FBS/BSA-free media were used to determine the cytotoxicity in each cell line. It is important to note that TAK-875 is highly bound to plasma proteins (99.8% in rats) (Otieno et al., 2018), so the addition of BSA to the caspase 3/7 activity experiment could cause the TAK-875 binding to BSA, and therefore the cytotoxicity effect could be attenuated. The mechanism underlining TAK-875-driven cell death has yet to be elucidated.

One of the main challenges in decreasing the high attrition rate in the drug discovery and development process is achieving a good balance between drug efficacy and potential adverse effects as early as possible (Bowes et al., 2012). The example of TAK-875, the development of which was terminated during phase III of clinical trials due to hepatotoxicity, showed that the safety profile should also be carefully studied as early as at the structure optimization process. Therefore, early profiling against a plethora of targets that are known to underlie ADRs, such as hERG (which is linked to cardiac arrhythmias) or the 5-hydroxytryptamine (serotonin) receptor 2B (which is linked to cardiac valvulopathy) was performed in this study and confirmed CPL207280’s selectivity of and lack of interaction with the tested off-targets (Table 2).

One of the proposed mechanisms of TAK-875 hepatotoxicity after multiple administrations in human is its long half-life and accumulation in the liver at high doses (Wolenski et al., 2017). Additionally, this half-life is longer in patients with type 2 diabetes compared with healthy volunteers (51.6 hours vs. 36.6 hours for a 50-mg dose) (Leifke et al., 2012; Naik et al., 2012). Results obtained from a pharmacokinetic study on Wistar Han rats demonstrated that in addition to the high bioavailability and concentration in the blood (Table 3), CPL207280 is characterized by a shorter half-life. This reduced the risk of accumulation during long-term administration. Despite this shorter half-life for CPL207280, its high activity still provides an antidiabetic effect, which has been demonstrated in animal studies.

Because CPL207280 exhibited a favorable effect as an insulin secretagogue in mouse insulinoma cells, subsequently, the glucose-lowering effects of CPL207280 were evaluated in vivo during GTT in healthy rodents. A single administration of CPL207280 reduced plasma glucose levels during GTT in healthy rats after both the first and the second glucose challenge (Fig. 7, A, C, D, and E). Notably, the administration of

CPL207280 in the fasted state did not have any effect on glucose levels prior to the GTT (Fig. 7A) in contrast to diabetic models, in which we observed stimulation of insulin secretion and glucose lowering (Figs. 8, A and C, 9, A and C, and 10, A and C) before the glucose load. Collectively, these observations indicate glucose dependence of CPL207280 and TAK-875 action. This corresponds with the results of the previous study demonstrating that TAK-875 did not increase the risk of hypoglycemia in patients with T2D (Leifke et al., 2012).

As postprandial hyperglycemia caused by insufficient insulin secretion in response to blood glucose levels is observed in patients with T2D (Wajchenberg, 2007; Leahy, 2005), we tested CPL207280 in GTT in different diabetic rat models (GK, ZDSD, ZDF). Provided that the T2D rat models used in this study represent different stages of diabetes or different phenotypes typically observed in humans, this study allows us to compare CPL207280 with other T2D drugs available on the market and meet the expectations of patients with T2D.
A ZDSD rat model was developed as an alternative to ZDF rats, which are a gold standard for diabetes studies. However, despite sharing many of the characteristics of the human condition, ZDF rats have a genetic defect in the leptin receptor, which is considered a disadvantage, and that makes them an artificial model (Peterson et al., 2015). Unlike ZDF rats, a ZDSD model exhibits type 2 diabetes with a long pre-diabetic condition in the presence of an intact leptin pathway. Animals demonstrate obesity, impaired glucose tolerance, insulin resistance, dyslipidemia, and prediabetic hypertension—symptoms reflecting the initial stage of diabetes development very well (Weir and Bonner-weir, 2004). In ZDSD rats, CPL207280 enhanced insulin secretion and reduced plasma glucose levels in GTT but also reduced blood glucose prior to the GTT in all tested concentrations (Fig. 8). Interestingly, glibenclamide used as a control, representing sulfonylureas, a class of medicines commonly used in T2D therapy, also significantly increased insulin concentration, immediately after administration, but was not effective in lowering glucose concentrations (Fig. 8B). Although a ZDF rat as a T2D model has some disadvantages, it also has many advantages and is one of the most popular models employed to demonstrate the antidiabetic activity of new compounds. In a ZDF rat, which develops obesity and high insulin resistance at a young age and then, with aging, progressively develops hyperglycemia, CPL207280 also

**Fig. 8.** Improvement of glucose tolerance and GSIS in diabetic ZDSD rats treated with CPL207280. The effect of oral administration of CPL207280 or TAK-875 on blood glucose and insulin concentration after a glucose challenge in fasted ZDSD rats was evaluated during GTT. Graphs present glucose concentrations (A) and glucose AUC (B), insulin concentrations (C), and corresponding insulin AUC (D). Data are presented as means ± S.D. (n = 7). The results were analyzed using one-way ANOVA (B and D) or two-way ANOVA (A and C) with Dunnett’s post hoc test vs. control. *P < 0.05; **P < 0.01; ***P < 0.001; ****P < 0.0001.
improved glucose tolerance of the subjects and induced their insulin secretion in a dose-dependent manner. Our findings support the previous results (Ito et al., 2013) showing that administration of TAK-875 in ZDF rats resulted in an improvement of glucose tolerance and fasting hyperglycemia (Fig. 10).

During progression toward diabetes, when the β-cell mass becomes inadequate at some critical point, glucose levels increase over a relatively short time (Weir and Bonner-weir, 2004). Some similarities to this diabetes stage are represented by the GK rat, which is a nonobese T2D model with a defective β-cell number and function, leading to insufficient insulin secretion. As GPR40 agonists act as insulin secretagogues, we explored whether CPL207280 can regulate glucose levels also in this diabetic phenotype. Interestingly, in this model, we also observed that a single oral administration of CPL207280 enhanced insulin secretion and reduced plasma glucose levels during GTT but also has a glucose-lowering effect prior to the glucose tolerance test (Fig. 9). This finding confirmed that a glucose-lowering effect exerted through a GPR40 agonist occurs only under the condition of an elevated glucose level in the blood, unlike SUs that act on β-cells to continuously secrete insulin independently of blood glucose levels, resulting in hypoglycemia. It is worth noting that, among the tested diabetic models, GK rats showed the least response to CPL207280 in terms of insulin AUC (Fig. 9). This observation suggests that treatment with CPL207280 may be less effective in those individuals whose β-cell function is substantially impaired.

Fig. 9. Improvement of glucose tolerance and GSIS in diabetic GK rats treated with CPL207280. The effect of oral administration of CPL207280 or TAK-875 on blood glucose and insulin concentration after a glucose challenge in fasted GK rats was evaluated during GTT. The graphs show glucose concentrations (A) and glucose AUC (B), insulin concentrations (C), and corresponding insulin AUC (D). Data are presented as means ± S.D. (n = 7) and were analyzed using one-way ANOVA (B and D) or by use of two-way ANOVA (A and C) with Dunnett’s post hoc test vs. control. *P < 0.05; **P < 0.01; ***P < 0.001; ****P < 0.0001.
Glucose-stimulated insulin secretion in vivo typically follows a biphasic time course and consists of a rapid and transient first phase followed by a sustained second phase (Barbosa et al., 1998; Rorsman et al., 2000). The first phase of insulin secretion is mediated by the pool of insulin secretory granules located near the plasma membrane, whereas the second phase involves the transport of insulin granules from an intracellular reserve pool to the plasma membrane (Wang and Thurmond, 2009). It was examined that GPR40 agonists potentiated the second phase of insulin secretion preferentially in pancreatic islets (Ferdaoussi et al., 2012).

The high and sustained insulin level observed in diabetic animal studies (Figs. 8C, 9C, and 10C) is probably the second phase of insulin release. The first phase of insulin secretion in response to the elevated blood glucose level in diabetic animal models occurred just after compound administration but was unnoticed. Therefore, we observed the glucose-lowering effect even before the insulin peak (Figs. 9A and 10A) or even before the glucose bolus administration (Fig. 8A).

In conclusion, in the present study, we demonstrate that CPL207280 exhibited favorable pharmacological effects in various T2D animal models representing and relevant to

![Graphs A, B, C, D showing blood glucose and insulin changes](Figures 10A, 10B, 10C, 10D)
different diabetes phenotypes without a detectable risk of hypoglycemia. Additionally, CPL207280 successfully completed a phase I trial and met its primary endpoint with no adverse safety signals detected (NCT04622111). Therefore, we propose the CPL207280 compound as a novel, glucose-lowering agent that overcomes the unmet medical needs of patients with T2D.
