ABSTRACT

Species differences in renal drug transporters continue to plague drug development with animal models failing to adequately predict renal drug toxicity. For example, adefovir, a renally excreted antiviral drug, failed clinical studies for human immunodeficiency virus due to pronounced nephrotoxicity in humans. In this study, we demonstrated that there are large species differences in the kinetics of interactions of a key class of antiviral drugs, acyclic nucleoside phosphonates (ANPs), with organic anion transporter 1 [(OAT1) SLC22A6] and identified a key amino acid residue responsible for these differences. In OAT1 stably transfected human embryonic kidney 293 cells, the $K_m$ value of tenofovir for human OAT1 (hOAT1) was significantly lower than for OAT1 orthologs from common preclinical animals, including cynomolgus monkey, mouse, rat, and dog. Chimeric and site-directed mutagenesis studies along with comparative structure modeling identified serine at position 203 (S203) in hOAT1 as a determinant of its lower $K_m$ value. Furthermore, S203 is conserved in apes, and in contrast alanine at the equivalent position is conserved in preclinical animals and Old World monkeys, the most related primates to apes. Intriguingly, transport efficiencies are significantly higher for OAT1 orthologs from apes with high serum uric acid (SUA) levels than for the orthologs from species with low serum uric acid levels. In conclusion, our data provide a molecular mechanism underlying species differences in renal accumulation of nephrotoxic ANPs and a novel insight into OAT1 transport function in primate evolution.

Introduction

Acyclic nucleoside phosphonates (ANPs), including adefovir, cidofovir and tenofovir, have become a key class of antiviral drugs due to many unique features such as their prolonged action and low resistance profile (De Clercq and Holý, 2005). However, nephrotoxicity remains a concern for the ANPs. For example, adefovir was not approved by the Food and Drug Administration for the treatment of human immunodeficiency virus infection because of pronounced nephrotoxicity at dosages of 60–120 mg/day (Mellors, 1999). Subsequently, the drug was approved at 10 mg/day for the treatment of hepatitis B infections. However, even at low doses, the drug still has the potential to cause nephrotoxicity after chronic administration, particularly in patients with pre-existing kidney disease. Furthermore, the product label for cidofovir, used in the treatment of cytomegalovirus, includes a recommendation that probenecid be coadministered with the drug. Finally, although rare, tenofovir has been associated with nephrotoxicity, including in Fanconi-Bickel syndrome (Dahlin et al., 2015).

The mechanism for nephrotoxicity of ANPs is related to accumulation of the drugs in renal proximal tubules (De Clercq and Holý, 2005). Studies suggest that cytotoxicity of these antiviral agents is increased 100-fold in cells expressing organic anion transporter 1 (OAT1) (Ho et al., 2000). In fact, OAT1, which is highly expressed in the basolateral membrane of renal tubule epithelial cells, plays an important role in the uptake of ANPs into proximal tubular cells (De Clercq and Holý, 2005; Uwai et al., 2007). OAT1-mediated accumulation of adefovir and cidofovir is associated with increased cellular toxicity in vitro assays (Ho et al., 2000) and as noted, probenecid, a potent inhibitor of OAT1, reduces the nephrotoxic effects of cidofovir in both cynomolgus monkeys and humans (Lacy et al., 1998).

Thus, the question of whether preclinical animal species orthologs of OAT1 exhibit transport kinetics similar to the human ortholog becomes important for predicting nephrotoxicity in humans. Currently, our knowledge of the differences in

ABBREVIATIONS: ANP, acyclic nucleoside phosphonate; A203, alanine at position 203; 6CF, 6-carboxyfluorescein; cyOAT1, cynomolgus monkey organic anion transporter 1; HBSS, Hanks’ balanced salt solution; HEK293, human embryonic kidney 293; hOAT1, human organic anion transporter 1; OAT1, organic anion transporter 1; SNP, single-nucleotide polymorphism; S203, serine at position 203; SUA, serum uric acid.

689
the antiviral drug transport kinetics of OAT1 among human and preclinical animal species orthologs is limited. For example, the \( K_m \) value of human OAT1 (hOAT1) for cidofovir and adefovir was found to be 5- to 9-fold lower compared with rat OAT1 (Cihlar et al., 1999). On the other hand, there were minimal species differences between hOAT1 and the ortholog from cynomolgus monkey in terms of localization in the kidney, as well as its \( K_m \) value and transport efficiency (\( V_{\text{max}}/K_m \)) for 11 substrates, including two antiviral drugs, acyclovir and zidovudine (Tahara et al., 2005).

Here, we hypothesized that there are large species differences in the kinetics of ANP uptake into cells via OAT1, which may contribute to species differences in renal accumulation of these potentially nephrotoxic antiviral drugs. We report that hOAT1 had a significantly lower \( K_m \) value for the antiviral drug tenofovir in comparison with OAT1 species orthologs from four commonly used preclinical animals, including cynomolgus monkey, mouse, rat, and dog. We demonstrated that serine at position 203 (S203), a residue predicted to be in the binding site of hOAT1, was essential for a lower tenofovir \( K_m \) value than alanine at the equivalent position. In addition, tenofovir transport efficiency (\( V_{\text{max}}/K_m \)) was higher for hOAT1 than for orthologs from the four preclinical animal species. Finally, we explored primate evolution of the transporter and noted that all apes consistently have S203, whereas most Old and New World monkeys have alanine at position 203 (A203). One of the remarkable characteristics of apes is that they have lost functional uricase during evolution (Kratzer et al., 2014), and consequently their serum uric acid (SUA) levels are significantly higher than species with uricase activity. Although speculative, our data suggest that S203 in OAT1, and consequently their serum uric acid (SUA) levels are significantly higher than species with uricase activity. Al-though speculative, our data suggest that S203 in OAT1, and consequently their serum uric acid (SUA) levels are significantly higher than species with uricase activity. Al-

Materials and Methods

Chemicals and Reagents

Adefovir, cidofovir, 6-carboxyfluorescein (6CF), and glutaric acid were purchased from Sigma-Aldrich (St. Louis, MO). Tenofovir was purchased from Carbosynth (Berkshire, United Kingdom). \( \alpha \)-Ketoglutarate was purchased from Spectrum Chemicals & Laboratory Products (Gardena, CA). \( ^{3}H \)-tenofovir and \( ^{3}C \)-uric acid were purchased from American Radiolabeled Chemicals (St. Louis, MO). The specific activities of these compounds were 10 and 50 mCi/mmol, respectively. \( ^{3}H \)-adefovir and \( ^{3}C \)-cidofovir were purchased from Moravek Inc. (Brea, CA). The specific activities of these compounds were 16.6 and 30.5 Ci/mmol, respectively. \( ^{3}P \)-a-phosphohippuric acid was purchased from PerkinElmer Health Sciences Inc. (Shelton, CT) with specific activity of 5 Ci/mmol. Cynomolgus monkey and dog whole kidneys were purchased from BioReclamationIVT (New York, NY). Samples of mouse and rat whole kidneys were provided by AstraZeneca (Waltham, MA).

Blast and Sequence Alignment. Human OAT1 amino acid sequence from 196 to 210 (GMALAGISLNCMTLN) was used to perform protein blast using the online tool BLAST (Altschul et al., 1997) (https://blast.ncbi.nlm.nih.gov/Blast.cgi?PROGRAM=blastp&PAGE_TYPE=BlastSearch&LINK_LOC=blasthome) to identify species with verified or predicted OAT1 amino acid sequences. OAT1 orthologs from proboscis monkey (Nasalis larvatus), hamadryas baboon (Papio hamadryas), and small-eared galago (Otolemur garnettii) were obtained from UCSC Genome Browser (https://genome.ucsc.edu/). OAT1 amino acid sequences were aligned using Clustal Omega (Goujon et al., 2010; Sievers et al., 2011; McWilliam et al., 2013) (http://www.ebi.ac.uk/Tools/msa/clustalo/).

Cloning and Establishment of Expression Vectors of Human, Cynomolgus Monkey, Mouse, Rat, Dog, Chimpanzee, Gorilla, Gibbon, Orangutan, and Galago OAT1 Orthologs. Polymerase chain reaction primers (Supplemental Table 1) based on the coding regions of OAT1 of human (NM_153276.2) was designed to amplify full-length fragments from our previous work (Kratzer et al., 2005). Polymerase chain reaction primers (Supplemental Table 1) based on the coding regions of cynomolgus monkey (NM_001287697.1), rat (NM_017224.2), and dog (XM_532582.5) were designed to amplify full-length fragments from kidney cDNAs (Zyagen, San Diego, CA) from corresponding species. The coding regions of mouse Oat1 (BC021647.1) were amplified from cDNA clones purchased from OriGene (Rockville, MD). The coding sequences of OAT1 from chimpanzee (XM_001160252.4), western lowland gorilla (XM_019397481.1), and northern white-cheeked gibbon (XM_003274115.1) were generated from hOAT1 using the Q5 Site-Directed Mutagenesis Kit (New England Biolabs, Ipswich, MA). Sumatran orangutan OAT1 (XM_002821628.1) and small-eared galago (XM_003798698.1) were synthesized by GenScript USA Inc. (Piscataway, NJ). OAT1 coding sequences were inserted in the pcDNA5/FRT plasmid to generate expression constructs.

Construction of Chimeric Transporters. Amino acid sequences of hOAT1 and cynomolgus monkey OAT1 (cyOAT1) were aligned and 17 different amino acids were identified between the two species. Chimeric proteins were constructed using NEBuilder HiFi DNA Assembly Cloning Kit (New England Biolabs). Three chimeric transporters (human 1–136 + cyOAT1: monkey 137–550), human 1–300 + cynomolgus monkey 301–550, and cynomolgus monkey 1–400 + human 401–550) were constructed. The sequence of each chimera was confirmed by DNA sequencing (MCLAB, South San Francisco, CA).

Cloning of Human and Cynomolgus Monkey OAT1 Mutants. Human OAT1 S203A and S203T, and cynomolgus monkey OAT1 S198A, A203S, I254V, and V256A were generated using the Q5 Site-Directed Mutagenesis Kit (New England Biolabs) according to the manufacturer’s protocol. Sequences were confirmed by DNA sequencing.

Transfection and Establishment of Stable Cell Lines. Genes encoding OAT1 orthologs and mutants were transfected in human embryonic kidney 293 (HEK293)-Flp-In cells (ThermoFisher Scientific, Waltham, MA) using Lipofectamine LTX (Life Technologies, Carlsbad, CA) according to the manufacturer’s protocol. HEK293-Flp-In cells stably transfected with the empty vector or the vector containing the genes of interest were grown in Dulbecco’s modified Eagle’s medium supplemented with 10% fetal bovine serum, penicillin (100 U/ml), streptomycin (100 \( \mu \)g/ml), sodium pyruvate (110 \( \mu \)g/ml), and hygromycin B (100 \( \mu \)g/ml) at 37°C in a humidified incubator with 5% CO_2.

Inhibition of hOAT1-Mediated 6CF Uptake by Adefovir, Cidofovir, and Tenofovir. The method as described in Liang et al., (2015) was used with minor modifications. Cells were seeded in black wall poly-D-lysine-coated 96-well plates for 24 hours to reach 95% confluence. Before the uptake experiment, cell culture medium was removed and the cells were washed with Hank’s balanced salt solution (HBSS). The inhibition of the uptake of 1 \( \mu \)M 6CF by OAT1 was performed at 37°C in the presence of antiviral drugs adefovir, cidofovir, and tenofovir at desired concentrations. The uptake was terminated at 1 minute. Cells were washed twice with ice-cold HBSS buffer. The IC_{50} values were calculated using GraphPad Prism 7 software (GraphPad Software Inc., La Jolla, CA).

Transporter Uptake Studies. The uptake was initiated by incubating transiently stably overexpressing cell lines with HBSS containing desired concentrations of a substrate. Cells were seeded in black wall poly-D-lysine-coated 96-well plates for 24 hours to reach 95% confluence. Before the uptake experiment, cell culture medium was removed and the cells were washed with HBSS. The details for drug concentrations and uptake time are described in Results and the
specific figures being cited. For the uric acid uptake assay, unlabeled uric acid was dissolved in 0.1 N NaOH and added to obtain designed concentrations in HBSS buffer plus 10 mM HEPES to maintain pH 7.4. The uptake was performed at 37°C, and then the cells were washed three times with ice-cold HBSS. Next, the cells were lysed with lysis buffer containing 0.1 N NaOH and 0.1% SDS, and the radioactivity in the lysate was determined by liquid scintillation counting. For the transporter study, the $K_m$ and $V_{max}$ values were calculated by fitting the data to a Michaelis-Menten equation using GraphPad Prism 7.

## OAT1 Comparative Structure Modeling and Docking.

Human OAT1 was modeled using the 2.9 Å crystal structure of a high-affinity phosphate transporter from *Perirnamospora indica,* in an inward-facing occluded state, with bound phosphate (Pedersen et al., 2013). The final sequence alignment was obtained by manual refinement of gaps in the output from the PROMALS3D (Pei et al., 2008) and MUSCLE (Edgar, 2004) web servers. One hundred models were generated using the automodel class in MODELER 9.16 (Sali and Blundell, 1993) and evaluated using the normalized discrete optimized protein energy (zDOPE) potential (Shen and Sali, 2006). The top-scoring model was then used for the prediction of a putative binding site near the location of the crystallographic phosphate with the FTMMap web server (Kozakov et al., 2015). Tenofovir was docked against the binding site with UCSF DOCK 3.6 (Coleman et al., 2013).

## Membrane Protein Extraction and Quantification.

The total membrane proteins were extracted using the ProteoExtract Kit (EMD Millipore, Billerica, MA). The final membrane fraction was diluted to a working concentration of 2 μg membrane protein per microliter as quantified by bicinchoninic acid assay. Total membrane proteins were reduced, denatured, alkylated, and digested in triplicate as per our previously reported protocol (Prasad et al., 2016). The OAT1 surrogate peptide, TSLAVLGK, generated by trypsin digestion, was quantified by liquid chromatography–tandem mass spectrometry, where the synthetic light peptide was used as the calibrator. The corresponding heavy peptide labeled at [13C6,15N2]lysine was used as the internal standard. Peptide quantification was performed using the Waters Xevo TQ-S tandem mass spectrometer coupled to Waters Acquity UPLC system (Waters, Hertfordshire, United Kingdom). An Acquity UPLC HSS T3 column (1.8 μm, 2.1 × 100 mm; Waters), with a Security Guard column (C18, 4 × 2.0 mm) from Phenomenex (Torrance, CA), was eluted (0.3 mL/min) with a gradient mobile phase consisting of water and acetonitrile (with 0.1% formic acid). The injection volume was 5 μL (~10 μg of total protein). The optimized liquid chromatography–tandem mass spectrometry parameters (Prasad et al., 2016) were used in electrospray ionization positive ionization mode. The data were processed by integrating the peak areas generated from the reconstructed ion chromatograms for the analyte peptides and the respective heavy internal standards using the MassLynx software (Waters). The OAT1 protein levels in the cells expressing the OAT1 orthologs from five species were measured; however, the OAT1 protein levels from cells expressing the mutant OAT1 proteins were not determined.

### Statistical Analysis.

Unless specified, data in all provided figures and tables are expressed as mean ± S.D. All experiments were performed at least twice with three to four replicates of each data point. Statistical analyses, as specified in the legends of all provided figures and tables, were performed to determine significant differences between controls and treatment groups. The data were analyzed using GraphPad Prism 7. A value of $P < 0.05$ was considered statistically significant.

## Results

### Inhibition of OAT1-Mediated 6CF Uptake by ANPs.

To determine whether there are species differences in the interaction kinetics of ANPs with OAT1, we first characterized the inhibition potencies of the three ANPs. Adefovir, cidofovir, and tenofovir inhibited uptake of 6CF in HEK293 cells stably expressing OAT1 orthologs from five species: hOAT1, cyOAT1, rat OAT1, mouse OAT1, and dog OAT1 (Fig. 1). Notably, the $IC_{50}$ values of adefovir and tenofovir for hOAT1 (71 ± 15 and 61 ± 14 μM, respectively, Table 1) were significantly lower than the values for OAT1 orthologs from the four preclinical animal species. Importantly, the $IC_{50}$ values of adefovir, cidofovir, and tenofovir for hOAT1 were 3.1-, 2.1-, and 5.6-fold, respectively, lower than the $IC_{50}$ values for cyOAT1, which has the greatest homology to hOAT1 compared with the other species orthologs studied.

### Kinetic Studies of Tenofovir Transport by hOAT1 and Four Common Preclinical Animals.

To further characterize species differences in the kinetics of the transporter for ANPs, we used [3H]-tenofovir as a model substrate. We selected tenofovir for more detailed studies because of its widespread use as an antiviral agent; however, key experiments were validated with adefovir and cidofovir (Fig. 3G). First, we compared the kinetics of uptake of [3H]-tenofovir in the stable cell lines recombinantly expressing hOAT1 or the orthologs from the aforementioned four preclinical animals. The $K_m$ value for hOAT1-mediated tenofovir uptake (72.6 ± 20 μM) was significantly lower than the respective $K_m$ values for OAT1 orthologs from cynomolgus monkey, mouse, rat, and dog (Table 2). Moreover, tenofovir transport efficiency ($V_{max}/K_m$) for hOAT1 was greater than its transport efficiency for cyOAT1 before and after normalization for total cell membrane-bound proteins (Fig. 2A; Table 2). As expected, the $V_{max}$ value of tenofovir for OAT1 orthologs was significantly correlated with the total cell membrane-associated quantity of OAT1 in the stable cell lines ($R^2 = 0.89$) (Fig. 2B; Supplemental Table 3). It should be noted that membrane-associated protein levels of the various species orthologs of OAT1 in transfected human embryonic kidney cells may not reflect quantities of OAT1 in the kidney tissue. Thus, in vivo maximum transport rates and efficiencies among the OAT1 orthologs may differ from what was observed in the cell lines. In fact, we found that the total cell membrane-bound protein level for hOAT1 was the highest in transfected HEK293 cells but the lowest among all the five species in the kidney cortex (Supplemental Table 3).

### Functional Characterization of Chimeric and Mutant Transporters.

CyOAT1 has 96.91% amino acid identity to hOAT1 (Supplemental Table 2) and yet its transport efficiency for cyOAT1 was comparable to that for hOAT1 (Supplemental Table 2) and yet its transport efficiency for hOAT1 (72.6 ± 20 μM) was significantly lower than the respective $K_m$ values for OAT1 orthologs from the four preclinical animal species.

To identify the essential domains and amino acid residues in hOAT1 responsible for the lower transport efficiency of hOAT1 (Supplemental Table 3) and yet its transport efficiency for hOAT1 (72.6 ± 20 μM) was significantly lower than the respective $K_m$ values for OAT1 orthologs from the four preclinical animal species.
uptake rate for cyOAT1 A203S was almost three times greater
than that of wild-type cyOAT1 (Fig. 3D), whereas no signifi-
cant changes in its uptake rate were observed for the other
three mutants. Next, we evaluated tenofovir transport in cells
expressing the corresponding mutation in hOAT1 (S203A),
which resulted in a 60% reduction in the rate of tenofovir
uptake (Fig. 3D). In addition, the $K_m$ value of tenofovir for
hOAT1 S203A (216 ± 19 μM) was significantly higher than for
hOAT1 wild type (72 ± 20 μM), whereas the $K_m$ value of
tenofovir for cyOAT1 A203S (105 ± 27 μM) was significantly
lower than for cyOAT1 wild type (254 ± 0.1 μM). Furthermore,
the $K_m$ value of tenofovir for cyOAT1 A203S was not signifi-
cantly different from hOAT1 wild type (Fig. 3E; Table 3).
These experimental results were further supported by the
docking results of tenofovir against a hOAT1 comparative
structure model. The $-\mathrm{PO}_3\mathrm{H}_2$ moiety is shown to form a
hydrogen bond with the side chain hydroxyl of S203 and Y230,
thus stabilizing tenofovir within the binding site (Supplemen-
tal Fig. 1) and S203A mutation eliminates this favorable
interaction. These results strongly suggest that S203 in
hOAT1 is important for the lower $K_m$ value of tenofovir.
Notably, the uptake rates of $[^3\mathrm{H}]$-adefovir and $[^3\mathrm{H}]$-cidofovir
for hOAT1 were significantly greater than those for cyOAT1
and hOAT1 S203A ($P < 0.0001$). Consistently, the uptake rate
of $[^3\mathrm{H}]$-adefovir for cyOAT1 A203S was significantly higher
than that for cyOAT1 ($P = 0.0001$). In contrast, the uptake
rate of $[^3\mathrm{H}]$-cidofovir for cyOAT1 A203S was not significantly
higher than that for cyOAT1 (Fig. 3G). In addition, since OAT1
functions as a substrate/α-ketoglutarate exchanger (Lu et al.,
1999), we measured hOAT1- and cyOAT1-mediated $[^3\mathrm{H}]$
tenofovir uptake after preincubation with 5 mM α-ketoglutarate
or glutaric acid for 120 minutes. Consistent with the previous
study (Lu et al., 1999), pretreatment with α-ketoglutarate and
glutaric acid significantly increased $[^3\mathrm{H}]$-tenofovir uptake
by both hOAT1 and cyOAT1 (Fig. 3H). α-Ketoglutarate
preincubation had a greater effect on tenofovir uptake by
cyOAT1 than by hOAT1 (1.45 times vs. 1.95 times tenofovir
uptake in the absence of α-ketoglutarate in cells expressing

![Fig. 1.](image-url) Species differences in the inhibition potencies of ANPs (adefovir, cidofovir, and tenofovir) for OAT1-mediated 6CF uptake. HEK293 cells stably
expressing hOAT1, cyOAT1, rat OAT1, mouse OAT1, and dog OAT1 were incubated with HBSS buffer containing 6CF (1 μM) for 1 minute with or without
designed concentrations of adefovir, cidofovir, and tenofovir. Data points represent the mean ± S.D. of 6CF uptake from three replicate determinations in
a single experiment. The experiments were repeated three times and similar results were obtained. Representative curves of the OAT1-mediated 6CF
uptake inhibition by ANPs: (A) Adefovir; (B) Cidofovir; (C) Tenofovir. The IC$_{50}$ values for each of the analogs with each OAT1 ortholog are listed in Table 1.

hOAT1 and cyOAT1, respectively). However, cyOAT1 transport activity remained significantly lower than hOAT1 transport activity after preincubation with α-ketoglutarate. These results suggest that α-ketoglutarate and glutaric acid stimulate the activity of OAT1 irrespective of whether an alanine or a serine is present at position 203. Additionally, an alanine at position 203 results in lower activity of OAT1 in comparison with a serine at the same position in the presence or absence of the counterion.

**Comparison of K\textsubscript{m} Values of Tenofovir for OAT1 Orthologs with Serine or Alanine.** Tenofovir uptake kinetics in stable cell lines recombinantly expressing OAT1 orthologs from chimpanzee, gorilla, orangutan, gibbon, squirrel monkey, and galago were determined to confirm the critical role of S203 in hOAT1-mediated tenofovir uptake. The mean value of K\textsubscript{m} (72.4 ± 20 μM) for seven OAT1 proteins with serine was significantly lower (P < 0.001) than the respective value for six OAT1 proteins with an alanine at the equivalent position (181 ± 46 μM) (Fig. 3F; Table 4).

**Association of OAT1-Mediated Tenofovir Transport Efficiency (V\textsuperscript{max}/K\textsubscript{m}) with Serum Uric Acid Levels.** Evolutionary studies reveal that uricase was lost during primate evolution (Kratzer et al., 2014) and consequently apes have significantly elevated SUA levels (Table 5). We observed that the mean value of OAT1-mediated tenofovir transport efficiency (V\textsuperscript{max}/K\textsubscript{m}) was significantly greater in apes (58.9 ± 8.3 μl/mg/min, N = 5) in comparison with species with much lower SUA levels (16.5 ± 5.3 μl/mg/min, N = 5, P < 0.0001) (Fig. 4A; Table 5). Intriguingly, all apes (human, chimpanzee, gorilla, orangutan, and gibbon) have a S203 (Table 4). In contrast, alanine is the only amino acid at the equivalent position in 12 OAT1 orthologs from Old World monkeys (Supplemental Table 4), which are the most closely related primates to apes. In addition, alanine is the dominant amino acid at the equivalent position in four OAT1 orthologs from New World monkeys. Importantly, Cebus capucinus, unlike the other three New World monkeys, maintains high SUA levels similar to human and has a T203 (Fanelli and Beyer, 1974). The [3H]-Tenofovir uptake rate in transiently transfected human embryonic kidney cells overexpressing hOAT1 S203T was 75% of hOAT1 wild type and 4.2 times that of cyOAT1 wild type (Fig. 4B). Furthermore, the K\textsubscript{m} value

Fig. 2. Kinetics of uptake of tenofovir for species orthologs of OAT1. (A) The uptake kinetics of [3H]-tenofovir in HEK293 cells expressing hOAT1, cyOAT1, rat OAT1, mouse OAT1, and dog OAT1. The uptake rate was evaluated at 3 minutes. Each point represents the mean ± S.D. uptake in the OAT1-transfected cells minus that in empty vector cells. (B) Correlation of the V\textsubscript{max} value of OAT1-mediated tenofovir uptake in HEK293 cells stably expressing five OAT1 species orthologs with total cell membrane-bound OAT1 protein quantity (R\textsuperscript{2} = 0.892).
of uric acid for hOAT1 (571 ± 97.7 μM) was significantly lower than its $K_m$ value for cyOAT1 (1070 ± 90 μM) (Fig. 5; Table 6). The differences in $K_m$ values of ANPs between cyOAT1 and hOAT1 were much greater than the 2-fold difference in $K_m$ values for uric acid in the two species. Nevertheless, the data suggest a potentially important endogenous role of S203 in apes.

Fig. 3. Chimera proteins of OAT1 created to assess the critical domains and residues involved in the species differences of tenofovir kinetics in cells stably expressing hOAT1 and cyOAT1. (A) Predicted membrane-bound hOAT1 structure showing 550 amino acids. The white color indicates amino acid residues that are conserved between hOAT1 and cyOAT1, the turquoise color shows residues that vary between hOAT1 and cyOAT1, and the orange color indicates residues that were mutated and evaluated for tenofovir transport kinetics. (B) Wild-type hOAT1, cyOAT1, and chimeric proteins with different combinations of hOAT1 and cyOAT1 amino acids. (C) $[^{3}H]$-tenofovir uptake by OAT1 chimera proteins. Transiently transfected HEK293 cells overexpressing chimera proteins were incubated with $[^{3}H]$-tenofovir (50 nM) for 3 minutes. (D) $[^{3}H]$-tenofovir uptake by cyOAT1 mutants (cyOAT1 S198A, A203S, I254V, and V256A) and hOAT1 mutant (hOAT1 S203A). Transiently transfected HEK293 cells overexpressing mutant proteins were incubated with $[^{3}H]$-tenofovir (50 nM) for 3 minutes. (E) Eadie-Hofstee plot for the $[^{3}H]$-tenofovir uptake by stable cell lines overexpressing hOAT1 and cyOAT1 and their mutants, hOAT1 S203A and cyOAT1 A203S. (F) Comparison of the averaged $K_m$ values for hOAT1 orthologs with S203 ($N$ = 7, including human, chimpanzee, gorilla, orangutan, gibbon, galago, and cynomolgus monkey OAT1 A203S) with that for OAT1 orthologs with alanine at the equivalent position ($N$ = 6, including cynomolgus monkey, squirrel monkey, mouse, rat, dog, and human OAT1 S203A). Student’s $t$ test was performed to determine significant differences between the two groups. (G) The uptake rate of $[^{3}H]$-adefovir and $[^{3}H]$-cidofovir in cells overexpressing hOAT1 and cyOAT1 and the mutants, hOAT1 S203A and cyOAT1 A203S. Each column represents the mean ± S.D. uptake in the OAT1-transfected cells minus that in empty vector cells. Two experiments were conducted and there were four replicates for each experiment. Statistical analyses were performed by one-way analysis of variance followed by Tukey’s multiple comparisons test to determine significant differences between controls and treatment groups. (H) The rate of uptake of $[^{3}H]$-tenofovir in HEK293 cells overexpressing hOAT1 or cyOAT1 with or without 120-minute preincubation with 5 mM α-ketoglutarate or 5 mM glutaric acid. Each bar represents uptake (mean ± S.D.) in the OAT1-transfected cells minus that in empty vector cells ($N$ ≥ 2). *$P$ value <0.05; **$P$ value < 0.01; ***$P$ value <0.001; ****$P$ value = 0.0001. n.s., not significant.
Discussion

Nephrotoxicity is a particular concern for many antiviral agents (De Clercq and Holy, 2005; Izzedine et al., 2005). To ensure the safety of healthy volunteers in first-in-human clinical studies, estimation of the maximum safe starting dose is essential, and the most widely used method is based on no observable adverse effect levels in multiple preclinical animal species (Zou et al., 2012). Transporters in the solute carrier superfamily are important determinants of tissue levels and subcellular distribution of many drugs (Leabman et al., 2003; Giacomini et al., 2010; Shima et al., 2010; Dahlin et al., 2013; Yee et al., 2013), and therefore play a role in drug toxicities. Thus, species differences in the activity or expression of solute carrier transporters may lead to failure to adequately predict drug toxicities in humans. For example, differences in subcellular expression levels of equilibrative nucleoside transporters 1 between rodents and humans led to the failure to predict the mitochondrial toxicity of fialuridine in humans that resulted in several deaths and withdrawal of the drug in phase I clinical trials (McKenzie et al., 1995; Lee et al., 2006). In this study, we focused on OAT1 because OAT1 expression greatly enhances the cytotoxicity of ANPs (Ho et al., 2000). In addition, the apparent failure to adequately predict the pronounced nephrotoxicity of adefovir (at 120 mg) in humans from preclinical studies in animal species (Benhamou et al., 2001) motivated us further to explore species difference in OAT1.

The major finding of this study was that there are large species differences in the uptake of ANPs via OAT1 (Table 1). Notably, tenofovir had a significantly lower $K_m$ value for hOAT1 than for OAT1 orthologs from cynomolgus monkey, mouse, rat, and dog (Table 2). Furthermore, substitution of S203 for alanine in cyOAT1 resulted in a significantly greater tenofovir transport rate (Table 3). These data suggest that hOAT1 transport may mediate a greater accumulation of ANPs in human proximal tubule cells than for OAT1 orthologs from preclinical animal species, and therefore play a role in drug toxicities. The high correlation between the $V_{max}$ value and total cell membrane-bound protein quantity among the five species (Fig. 2B; Supplemental Table 3) suggests that the turnover rate for tenofovir by OAT1 orthologs from the five species was similar.

There have been many studies examining the molecular basis of OAT1 function, and identifying critical amino acid residues and domains of the protein responsible for substrate recognition and translocation (Tanaka et al., 2004; You, 2004; Perry et al., 2006; Xu et al., 2006; Hong et al., 2007a,b; Rizwan et al., 2007; Keller et al., 2011). Importantly, we report that S203 in hOAT1 is a key determinant of the lower $K_m$ value of tenofovir. Notably, compared with all of the amino acid residues in hOAT1 previously reported to be involved in the transport of ANPs—R50 (Bleasby et al., 2005), Y230 (Perry et al., 2006), and F438 (Perry et al., 2006)—S203 is the only amino acid that is different between hOAT1 and the orthologs from cynomolgus monkey, mouse, rat, and dog. It is worth noting that there was no significant species difference in the $K_m$ value for the canonical substrate of OAT1, p-aminohippuric acid, between hOAT1 and cyOAT1 (Supplemental Fig. 2; Supplemental Table 5), suggesting that species differences in OAT1 orthologs are substrate dependent. These results have implications for drug development since they suggest that allometric scaling may be used to predict renal accumulation of some OAT1 substrates (e.g., p-aminohippuric acid), but not others (e.g., tenofovir).

The maximal plasma concentrations for tenofovir in both humans (range 0.72–1.0 μM, oral dose of 300 mg) and rhesus macaques (range 1.28–2.3 μM, oral dose of 30 mg) (Kearney et al., 2004; Best et al., 2015) are well below their respective $K_m$ values (Table 2). Thus, OAT1-mediated tenofovir transport into proximal tubule cells of both humans and monkeys will be inversely correlated with their respective $K_m$ values (Table 2). Although the plasma concentrations of tenofovir are somewhat lower in humans than in monkeys at therapeutic doses, a greater accumulation of tenofovir in human proximal tubule cells may be predicted based on the lower $K_m$ value of tenofovir for hOAT1 (Table 2).

Although OAT1 transports tenofovir into the proximal tubule cell across the basolateral membrane, multidrug resistance protein type 4 transports the drug from the cell into the lumen during active tubular secretion (Ray et al., 2006). In

S, Serine; A, Alanine.
fact, cells expressing multidrug resistance protein type 4 are 2- to 2.5-fold less susceptible to tenofovir-induced cytotoxicity. In addition, to become pharmacologically active or cytotoxic, tenofovir requires phosphorylation by intracellular nucleotide kinases (Ho et al., 2000; Lade et al., 2015). Thus, multidrug resistance protein type 4 and nucleotide kinases, in addition to OAT1, may directly affect levels of tenofovir and other ANPs in the proximal tubule, and modulate renal toxicity.

Of particular interest is that S203 is conserved in all of the apes sequenced and archived in the National Center for Biotechnology Information database and UCSC Genome Browser to date (as of when this paper was submitted), including human, chimpanzee, pygmy chimpanzee, gorilla, orangutan, and gibbon (Supplemental Table 4). In contrast, most primates and more distant species from humans have an alanine at the equivalent position. Apes lost functional uricase during evolution (Kratzer et al., 2014) and subsequently SUA levels increased 2–17 times (Table 5). Uricase is responsible for the hydrolysis of uric acid to the more water-soluble product, allantoin, in the purine degradation pathway.

**Table 5.** OAT1-mediated tenofovir transport efficiencies and SUA levels in species with or without functional uricase. *The mean value of SUA was calculated based on reported levels. The range of SUA is included in parenthesis. —, not applicable.

![Image](https://example.com/image.png)

**Fig. 4.** Association of OAT1-mediated tenofovir transport efficiency (V_{max}/K_m) with SUA levels and effect of amino acid substitutions in hOAT1 on tenofovir uptake rate. (A) Mean ± S.D. of SUA levels (black bar) and OAT1-mediated tenofovir transport efficiencies (gray bar) in species with (cynomolgus monkey, squirrel monkey, mouse, rat, and dog) and without (human, chimpanzee, pygmy chimpanzee, gorilla, orangutan, and gibbon) functional uricase (* represents comparison of SUA levels in species with and without uricase; # represents comparison of tenofovir transport efficiencies in species with and without uricase; **P < 0.01; ###P < 0.0001). (B) [³H]-tenofovir uptake by hOAT1, cyOAT1, and mutants (hOAT1 S203T and hOAT1 S203A). Transiently transfected HEK293 cells overexpressing wild-type or mutant proteins were incubated with [³H]-tenofovir (50 nM) for 3 minutes. Transporter-mediated tenofovir uptake was obtained after subtracting the respective rate of uptake in empty vector cells.
Mammals possessing a functional uricase typically have low SUA levels. It should be noted that 70% of daily uric acid disposal occurs via the kidneys and its excretion and reabsorption are regulated by several renal transporters (Vitart et al., 2008; So and Thorens, 2010). Polymorphisms in genes encoding these transporters, such as SLC22A12, SLC2A9, and ABCG2, are associated with high SUA levels and gout (Graessler et al., 2006; Vitart et al., 2008; Kolz et al., 2009; Woodward et al., 2009). It was not previously known that the SLC22A6 locus is associated with SUA levels or gout in genome-wide association studies. However, a recent genome-wide association study in 109,029 Japanese populations (Kanai et al., 2018) showed that single-nucleotide polymorphisms (SNPs) within the SLC22A6 locus are significantly associated with SUA levels with the top SNP (rs148838714) at a P value of 3.5 \times 10^{-34} (see Supplemental Fig. 4; Supplemental Table 6). Although the function of the SNPs within this locus is not currently known, some of these SNPs within the locus are more common in Japanese populations. Future studies are needed to characterize the function of these variants, and perhaps through sequencing analysis to identify the causative variant that affects SUA.

Our kinetic data showing that uric acid has a lower $K_m$ value for hOAT1 than for cyOAT1 (Fig. 5; Table 6) show similar trends as in the kinetic data for URAT1 and suggest that OAT1 with S203 potentially evolved to more efficiently transport uric acid in apes. We also note that threonine at position 203, which is present in OAT1 from Cebus capucinus imitator, an Old World monkey that maintains high SUA levels (Fanelli and Beyer, 1974), results in similar transport efficiency as serine at the equivalent position (Fig. 4B). Thus, either a serine or a threonine may suffice at position 203 to confer greater OAT1 transport efficiency. The data are consistent with the evolution of alanine to serine or threonine in OAT1 to accommodate high levels of uric acid.

In conclusion, our study indicates that there are large species differences in the kinetics of interaction of OAT1 for ANPs. S203 contributes to the lower $K_m$ value for tenofovir and uric acid for hOAT1, suggesting a novel molecular mechanism underlying species difference in the kinetics of interaction of OAT1 with ANPs. Furthermore, S203 is conserved in apes with loss of uricase and subsequent elevated SUA levels, suggesting a potentially important role in uric acid excretion in primate evolution. Finally, our results suggest that typical species used in preclinical toxicology studies may not recapitulate OAT1-mediated drug accumulation in the kidney, resulting in poor ability to predict nephrotoxicity for drugs that are substrates of OAT1.
