ABSTRACT

Glutamatergic synaptic transmitters are cleared from the synaptic cleft through excitatory amino acid transporters (EAATs) that are responsible for recycling glutamate and transporting it into neurons and glial cells. To probe the structural role of the TM4b-4c loop of EAAT1 (Rattus norvegicus), each of the 57 amino acid residues was mutated to cysteine. Thirteen of the single mutants have very low transport activity. Aqueous accessibility of the introduced cysteines from the remaining mutants was then explored by membrane-permeant and membrane-impermeant sulfhydryl reagents in different conditions. F190C, V238C, and A243C were affected by permeant and membrane-impermeant sulfhydryl reagents in inversely, L244C was protected by glutamate. The modification of A243C by MTSEA was enhanced by either potassium and glutamate or threo-β-benzylaspartate. From these results, we suggest that residues F190C, V238C, and A243C may be responsible for the inward-facing conformation of the transporter. Inversely, L244C was protected by glutamate. The modification of A243C by MTSEA was enhanced by either potassium and glutamate or threo-β-benzylaspartate. From these results, we suggest that residues F190C, V238C, and A243C may be located near the extracellular surface, and the TM4b-4c loop forms multiple reentrant membrane loops on the cell surface. Alternatively, F190C, V238C, and A243C may function in the transport pathway, which is exposed to MTSET. In addition, Q189C, A243C, and L244C are conformationally sensitive and may play a role in the transport cycle.

Introduction

Glutamate is the predominant excitatory transmitter in the central nervous system. To prevent hyperexcitability and neurotoxicity, it is recycled from the synapse cleft by excitatory amino acid transporters (EAATs) that are responsible for recycling glutamate and transporting it into neurons and glial cells (Kanner and Schuldiner, 1987; Nicholls and Attwell, 1990; Rothstein et al., 1996; Zerangue and Kavanaugh, 1996; Tanaka et al., 1997; Levy et al., 1998). Glutamate transporters play an important role in terminating synaptic excitation (Tong and Jahr, 1994; Otis et al., 1996; Diamond and Jahr, 1997; Verdon et al., 2014).

Glutamate transport is an electrogenic translocation generated by the Na+/K+ -ATPase (Kanner and Sharon, 1978; Brew and Attwell, 1987; Wadiche et al., 1995). To maintain steep transmembrane glutamate gradients, EAATs transport one substrate molecule in symport with three sodium ions and one proton. In the second half-cycle, one potassium ion is released to the extracellular space and the next cycle of transporter starts (Zerangue and Kavanaugh, 1996; Levy et al., 1998; Owe et al., 2006). There are five known subtypes of EAATs: EAAT1, GLT-1, excitatory amino acid carrier-1, EAAT4, and EAAT5. Also, they share about amino acid identity of 50% (Kanai and Hederger, 1992; Pines et al., 1992; Storeck et al., 1992; Arirza et al., 1994, 1997; Fairman et al., 1995).

The crystal structures of aspartate transporter from the archaeon glutamate transporter homolog from Pyrococcus horikoshii (GltPh) have advanced our understanding of eukaryotic glutamate transporters and provided insights into various aspects of transport, in accordance with biochemical, electrophysiological, and other experimental data (Yernool et al., 2004; Boudker et al., 2007; Kanner, 2007; Crisman et al., 2009; Reyes et al., 2009; Teichman et al., 2009; Verdon and Boudker, 2012). The structure illuminates a trimer with a permeation pathway through each of the monomers, suggesting that the monomer is the fully independent and functional unit. The same is true for the eukaryotic glutamate transporters (Grewer et al., 2005; Koch and Larsson, 2005; Koch et al., 2007a; Leary et al., 2007). The functional unit is a monomer containing eight transmembrane domain (TM) helices (TM1 ~ TM8) and two

ABBREViations: ChCl, choline chloride; CL-EAAT1, cysteine-less excitatory amino acid transporter 1; DL-TBOA, dl-threo-β-benzylaspartate; EAAT, excitatory amino acid transporter; FRET, fluorescence resonance energy transfer; GLT-1, glial glutamate transporter type 1; GLTPh, glutamate transporter homolog from Pyrococcus horikoshii; HP, hairpin loop; MTSEA, 2-aminoethyl methanethiosulfonate; MTSET, (2-trimethylammonium)-ethyl methanethiosulfonate; TM, transmembrane domain.
oppositely oriented re-entrant loops (HP1 and HP2) (Boudker et al., 2007; Shrivastava et al., 2008; Reyes et al., 2009; Canul-Tec et al., 2017). HP1 and HP2 are located on opposite sides of the cell membrane. HP2 participates in the extracellular gating for the substrate reaction, whereas HP1 has been postulated to form the intracellular gate (Yernool et al., 2004; Huang and Tajkhorshid, 2008; Shrivastava et al., 2008; Crisman et al., 2009; Reyes et al., 2009). The amino acid insertions and deletions, together with the differences on the transport function and pharmacology of GltPh, make it impossible to uncover the structural mechanism of the EAATs. The TM4 domain in EAATs is composed of three separate helices—4a, 4b, and 4c—with GltPh sharing about 35% sequence identity with EAAT1 (Fig. 1). The latter has 57 more amino acid residues located in the TM4b-4c loop (Yernool et al., 2004). To study the molecular and structural determinants in glutamate transport, we introduced a cysteine residue to replace each of the amino acids within the TM4b-4c loop of a cysteine-less EAAT1 (CL-EAAT1) (Seal and Amara, 1998). Membrane-permeant (2-trimethylammonium)ethyl methanethiosulfonate (MTSET) and membrane-impermeant 2-aminoethyl methanethiosulfonate (MTSEA) sulfhydryl reagents were used to explore the aqueous accessibility of introduced cysteines under conditions of either inward-facing or outward-facing conformations. Residues F190C, V238C, and A243C were sensitive to MTSET. These results suggest that residues in the TM4b-4c loop domain may participate in forming an aqueous transport pathway or may be located at the side, with Q189, A243, and L244 directly involved in the transport cycle.

**Materials and Methods**

**Generation of Mutants.** CL-EAAT1 in the vector pBluescript SK (−) (Stratagene, La Jolla, CA) was used as the parent template for site-directed mutagenesis. Mutant transporters were generated using the QuikChange Site-Directed Mutagenesis Kit (TOYOBO, Osaka, Japan). All mutant sequences were confirmed by full-length sequencing (Invitrogen, Waltham, MA). The latter has 57 more amino acid residues located in the TM4b-4c loop (Yernool et al., 2004; Canul-Tec et al., 2017). Insertions in TM4b-4c loop (Yernool et al., 2004; Canul-Tec et al., 2017). Insertions in TM4b-4c loop on GltPh (Yernool et al., 2004). "——"

**Cell Growth and Expression of Transporter.** HeLa cells purchased from the American Type Culture Collection (Manassas, VA) were cultured in Dulbecco’s modified Eagle’s medium basic 1× (Invitrogen) with 8% fetal calf serum (Invitrogen), 200 U/ml penicillin (Beyotime Biotechnology, Shanghai, People’s Republic of China), and 200 μg/ml streptomycin (Beyotime Biotechnology). Infections with recombinant vaccinia/T7 virus in serum-free Dulbecco’s modified Eagle’s medium basic 1× were carried out for 30 minutes (Fuerst et al., 1986). CL-EAAT1 or mutant constructs were then added into the virus-infected HeLa cells with Lipofectamine Transfection Reagent (Beyotime Biotechnology) and incubated at 37°C and 5% CO2 for 20 hours.

**Transport Assay.** Cells that expressed mutants in 24-well plates were washed with choline chloride (ChCl) solution (5 mM KPi, pH 7.4, 150 mM ChCl, 0.5 mM MgSO4, and 0.3 mM CaCl2) and incubated with NaCl solution (5 mM KPi, pH 7.4, 150 mM NaCl, 0.5 mM MgSO4, 0.3 mM CaCl2) containing 0.4 μM (15 μM D-[3H]-aspartate (PerkinElmer, Waltham, MA) for 10 minutes. The reaction was stopped using ice-cold NaCl solution and lysed with 1% sodium dodecyl sulfate. Finally, radioactivity was assayed (Fuerst et al., 1986).

**Inhibition Studies with Sulfhydryl Reagents.** Cells that expressed mutants in 24-well plates were washed once with ChCl solution. NaCl solution containing varying concentrations of MTSET (Biotium, Fremont, CA) or MTSEA (Biotium) were incubated at 37°C for 5 minutes. Cells were then washed twice with NaCl solution and transport activity was subsequently measured. The concentrations of the sulfhydryl reagents were optimized for each mutant to show a partial inhibition.

**Effects of Transporter Substrates and Inhibitors on Sulfhydryl Modification.** The following reagents were each supplemented to the preincubation media, along with MTSET or MTSEA, for the following inhibition assays: 150 mM NaCl solution, and 150 mM NaCl solution + 1 mM L-glutamate, 150 mM NaCl solution + 20 μM D-[3H]-TBOA (Tocris Bioscience, Bristol, UK), 150 mM KCl solution, and 150 mM ChCl solution.

**Cell Surface Biotinylation.** HeLa cells that expressed CL-EAAT1 and the mutants A243C and L244C were washed in a 6-cm dish with ice-cold phosphate-buffered saline (pH 8.0) after transfection for 24 hours. The cells were then incubated with ice-cold phosphate-buffered saline containing 0.5 mg/ml EZ-Link Sulfo-NHS-S-S-Biotin (Thermo Fisher Scientific, Waltham, MA) for 20 minutes with gentle shaking. The reaction was stopped with 100 mM glycine. The cells were then lysed on ice for 20 minutes with cell lysis buffer (Beyotime Biotechnology). The cell debris was separated by centrifugation at 12,000 rpm for 20 minutes at 4°C. Pierce Streptavidin Agarose (Thermo Fisher Scientific) beads were added to the supernatant and incubated for 40 minutes. The beads were then separated by centrifugation (1 minute at 4°C) and washed three times with ice-cold buffer, collecting the supernatants from each step into fresh tubes. Biotinylated proteins were separated from the streptavidin agarose beads by heat denaturation. Supernatants collected from each centrifugation step were subsequently analyzed using Western blots (Fuerst et al., 1986; Rong et al., 2016).

**Western Blot Analysis.** Protein samples were incubated in protein loading buffer at 55°C for 30 minutes prior to separation by gel electrophoresis (Laemmli, 1970) on a 10% Mini-PROTEAN gel. Gels were then stained with Coomassie brilliant blue R250 (Beyotime Biotechnology) and imaged. Bands were quantified using ImageJ (Abramoff et al., 2004). Densitometry was performed using the ImageJ plug-in “Image J” (Abramoff et al., 2004). The results were expressed as the fold change in protein expression compared to the respective control (Yernool et al., 2004).

**Fig. 1.** Sequence alignment and EAAT transmembrane topology. (A) Sequence alignment of TM4b-4c loop on GltPh and EAAT1 (Yernool et al., 2004; Canul-Tec et al., 2017). Insertions in eukaryotic transporters between helices 4b and 4c are not included and are marked by “——”. Arrows represent residues Q189, F190, V238, A243, and L244 on GltPh, and G149, V151, and L152 on EAAT1. (B) Representation of EAAT transmembrane topology (Yernool et al., 2004). Putative position of the 4b-4c loop is depicted by the red loop. Arrows represent the TM4b-4c loop.
Results

Cysteine Scanning and Transport Activity of Single Cysteine Mutants. Fifty-seven single cysteine mutants were generated by replacing each of the amino acid residues within the TM4b-4c loop of CL-EAAT1 to a cysteine residue. EAAT1, CL-EAAT1, and the mutants were expressed in HeLa cells, and the uptake of d-[3H]-aspartate was measured and compared with that of CL-EAAT1. The uptake ability of the cysteine mutants ranged from 1.5% ± 0.8% to 10.2% relative to CL-EAAT1. Thirteen mutants (K191C, T192C, Y194C, R197C, N206C, S218C, E230C, P233C, P235C, N242C, and G245C) had transport activities less than 15%. Transport activity of these mutants decreased gradually within the TM4b-4c loop of CL-EAAT1 to a cysteine residue. EAAT1, CL-EAAT1, and the mutants were expressed in HeLa cells, and the uptake of d-[3H]-aspartate was measured and compared with that of CL-EAAT1. The uptake ability of the cysteine mutants ranged from 1.5% ± 0.8% to 10.2% relative to CL-EAAT1. Thirteen mutants (K191C, T192C, Y194C, R197C, N206C, S218C, E230C, P233C, P235C, N242C, and G245C) had transport activities less than 15%. Transport activity of these mutants decreased gradually within the TM4b-4c loop of CL-EAAT1 to a cysteine residue.

Accessibility of Single Cysteine Mutants. To probe for sulfhydryl modifications on the extracellular side of the bilayer, HeLa cells expressing either CL-EAAT1 or each of the 44 single cysteine mutants demonstrating measurable transport activity were treated with membrane-impermeant sulfhydryl reagent, MTSET at 2.0 mM. Transport activities of F190C, V238C, and A243C were inhibited by MTSET (Fig. 3A) in a concentration-related way, with full inhibition of activity observed at 3.0 mM MTSET (Fig. 3B). The others were not impacted by MTSET. Additionally, the cells were exposed to membrane-permeant MTSEA at 2.5 mM to investigate the sulfhydryl modifications on the cytoplasmic side of the bilayer (Fig. 4A). Significant inhibition of the uptake activity of Q189C was detected (Fig. 4, A and C), whereas less inhibition was seen in F190C, V238C, A243C, and L244C (Fig. 4, A and B). Transport activity of these mutants decreased gradually with increasing MTSEA concentration (Fig. 4, B and C).

Effect of Transporter Substrates and Inhibitors on Sulfhydryl Modification in Single Cysteine Mutants. To increase exposure of the mutated residues to sulfhydryl modification, the cells were preincubated in media containing transporter substrates or inhibitors. Transport activities were measured on HeLa cells expressing Q189C, F190C, V238C, A243C, and L244C that were preincubated in the presence of the sulfhydryl reagent with saturating amounts of transporter substrates or inhibitors. Transporter substrates or inhibitors did not affect sulfhydryl modification of F190C and V238C by MTSET (Fig. 5) and MTSEA (Fig. 6, B and C). Potassium slightly enhanced MTSEA modification in Q189C and L244C, whereas DL-TBOA did not show a significant effect (Fig. 6, A and E). However, glutamate protected L244C from MTSEA modification (Fig. 6E). Last, transporter substrates or inhibitors enhanced MTSEA modification of L244C (Fig. 6D).
there was a pronounced decline in the cell surface expression of L244C (Fig. 7C). Compared with CL-EAAT1, the ratio of biotinylated proteins to nonbiotinylated proteins dramatically decreased in L244C but not in A243C (Fig. 7E). Comparable to the cysteine-less parent, transport activity normalized to relative plasma membrane expression of A243C and L244C decreased (Fig. 7F).

**Discussion**

Our previous results have demonstrated that the glutamate transporter EAAT1 may experience complicated movement between TM4 and HP1 or HP2 in the process of substrate transport (Rong et al., 2014). Also, we demonstrated that glutamate transporter GLT-1 undergoes a complicated conformational shift between TM2 and TM4 domains during transport cycle (Rong et al., 2016). There are 50 more amino acid residues in mammalian EAATs than bacterial protein in the TM4b-4c loop (Yernool et al., 2004) (Fig. 1). We introduced cysteine residues at each residue from Q189 to G245 to determine the accessibility and functionality of the TM4b-4c loop. Transport activities of 13 mutants were less than 15% and do not warrant further investigation. Aqueous accessibility of individual cysteines was determined by membrane-impermeable MTSET and membrane-permeable MTSEA. This reaction can lead to variable degrees of loss of function of the membrane protein, depending on the location of the cysteine and the importance of that position to the function of the protein. F190C, V238C, and A243C were sensitive to MTSET (Fig. 3A). We also observed that MTSEA inhibited the transport activity of Q189C, F190C, V238C, A243C, and L244C (Fig. 3B). This result, coupled with our findings on the membrane-impermeant sulphydryl reagent reactivity of other cysteine-substituted residues suggested that Q189 and L244 are located in an aqueous pore within the membrane, whereas F190, V238, and A243 may be located around the extracellular side of the plasma membrane. Additionally, the transport activity inhibition of Q189C with MTSEA is the highest compared with the other residues, indicating that this residue is quite accessible. Intersubunit distance measurements showed that the TM4b-4c loop is situated on the outer circumference of EAAT1. Koch and others have suggested that it may form a loop that extends from the entrance hall to the outer edge of EAATs and back to the core (Koch et al., 2007b). It was also postulated that
the TM4b-4c loop may exert effects on the coordination of the cooperativity of the three subunits for the binding of Na\(^{+}\) ions (Koch et al., 2007b). A previous study postulated that the TM4b-4c loop may be located on the extracellular vestibule of glutamate transporters (Yernool et al., 2004). In addition, the TM4b-4c loop of EAATs have previously been speculated to be accessible to the extracellular space (Pines et al., 1992; Grunewald et al., 1998; Seal et al., 2000). Our aqueous accessibility data indicated that the TM4b-4c loop may not simply be situated on the extracellular side of the membrane. It may form multiple reentrant membrane loops at the cell surface that lead to the MTSET modification of F190C, V238C, and A243C. Additionally, the results of MTS modification suggest a nonperiodic secondary structure.

Five single cysteine mutants, Q189C, F190C, V238C, A243C, and L244C, whose mutated residues are roughly situated at...
opposite ends of the TM4b-4c loop, are sensitive to the sulfhydryl compounds MTSET or MTSEA. To maximize the chances of sulfhydryl modification of these mutants from either side of the membrane, the cells were exposed to the sulfhydryl reagent in the presence of different external media. DL-TBOA, a nontransported and competitive inhibitor of EAAT1, is expected to increase the percentage of outward-facing transporters (Boudker et al., 2007). Conversely, the binding of L-glutamate may block access of the sulfhydryl reagents to the cysteine side chain. It is expected that potassium and glutamate will increase the percentage of inward-facing transporters (Bergles et al., 2002; Reyes et al., 2009). The explanation for the increased inhibition of transport by MTSEA in the presence of potassium is that when the transporter becomes inward facing, mutants Q189C, A243C, and L244C may move and become more accessible (Fig. 6, A, D, and E). However, L-glutamate protects the L244C from modification by MTSEA (Fig. 6E). For A243C, glutamate, potassium, and DL-TBOA each augmented the transporter activity inhibition by MTSEA (Fig. 6D). It may be explained that A243C accessibility increased in both outward-facing and inward-facing transporters during the transport cycle. Our previous results have demonstrated that A243C is accessible to MTSET, and inhibition was augmented in the presence of DL-TBOA (Rong et al., 2016). Our current results show that the inhibition of uptake activity of A243C by MTSEA is augmented in the presence of potassium and L-glutamate, but inhibition by MTSET is unaffected by these compounds. Presumably, MTSEA may be able to reach the cysteine at position A243C from both the outside and the inside of the cell membrane. F190C and V238C were not impacted by MTSET or MTSEA in the presence of TBOA or potassium and glutamate (Fig. 4, A and B; Fig. 5, A and B). Thus, for cysteine mutants F190C and V238C, this reactivity is not conformationally sensitive, suggesting that they are always accessible to the extracellular side or transport pathway. To investigate whether the loss of uptake activity detected
with A243C and L244C was owing to an absence of the transporter at the cell surface or whether these have intrinsic transport defects, the levels of the mutant proteins in the plasma membrane were evaluated by cell surface biotinylation. The decreased transport activity of L244C can be partially explained by the inability of the transporter to traffic or insert into the plasma membrane because of its absence from the biotinylated fraction (Fig. 7, C and E). A243C showed about 90% activity compared with CL-EAAT1. Uptake activity normalized to relative cell surface expression shows that A243C and L244C have an intrinsic transport defect (Fig. 7F).

Previous studies suggest state-dependent trypsin cleavage sites and conformational changes have been found between

**Fig. 7.** Membrane expression of V243C and V244C mutants. HeLa cells were transfected with the CL-EAAT1, V243C, and V244C mutants. (A) The total proteins, biotinylated membrane proteins, and nonbiotinylated proteins were measured by Western blot as described in Materials and Methods. Blots of all proteins were probed with the anti-EAAT1 antibody. Each blot of the biotinylated membrane proteins was probed for the internal plasma membrane marker integrin and the absence of α/β-tubulin, an endogenous cytosolic protein representing the negative control in the biotinylated membrane proteins. Each blot of the nonbiotinylated proteins was probed for the presence of α/β-tubulin. Each blot of the total proteins was probed for the presence of actin. (B) Densitometric analysis of the total proteins for each mutant normalized to internal marker (actin) and represented as a percentage of CL-EAAT1. (C) Densitometric analysis of the biotinylated membrane proteins for each mutant normalized to an internal marker (integrin) and represented as a percentage of CL-EAAT1. (D) Densitometric analysis of the nonbiotinylated proteins for each mutant normalized to an internal marker (α/β-tubulin) and represented as a percentage of CL-EAAT1. (E) The ratio of the biotinylated membrane protein expression and nonbiotinylated protein expression of CL-EAAT1 and mutants. (F) D-[3H]-Asp uptake activity normalized to relative cell surface expression. Values represent the mean ± S.E. of at least three different experiments performed in triplicate. Values significantly different from those of CL-EAAT1 were determined by one-way analysis of variance (*P < 0.05).
TM3 and TM4 on GLT-1 (Grunewald and Kanner, 1995; Bergles et al., 2002). This is consistent with our data. Conversely, fluorescence resonance energy transfer (FRET) results suggested little conformational change of the TM4b-4c loop during the transport cycle (Koch and Larsson, 2005). However, FRET measurements were the mean FRET efficiency, and they cannot uncover true complex conformational changes during the glutamate transport cycle. Large-scale transport domain movements were observed by single-molecule FRET imaging in a bacterial homolog of glutamate transporters (Akyuz et al., 2013). Therefore, FRET measurements may not accurately predict movement of the TM4b-4c loop. A previous study postulated that the TM4b-4c loop may be located in the extracellular vestibule of eukaryotic EAATs (Yernool et al., 2004), but this hypothesis is inconsistent with our results. N-Glycosylation sites in the TM4b-4c loop suggest these may play an important role in the post-translational processing of these proteins (Canul-Tec et al., 2017).

From the discussion above, we suggest that the majority of the residues in the TM4b-4c loop may form multiple reentrant membrane loops. Q189C, A243C, and L244C of the TM4b-4c loop are conformational sensitive and may have roles in the transport pathway during the transport cycle. The function of other residues of the TM4b-4c loop is not clear. The TM4b-4c loop may be located in the periphery of the transporter, based on the SWISS-MODEL (Fig. 8). Additionally, the result of the MTS experiment combined with the SWISS-MODEL suggested that some residues of the TM4b-4c loop may be positioned at the transport domain of the protein.

**Fig. 8.** Structure model from 5llm.1.A. Three-dimensional image of EAAT1 was generated by the SWISS-MODEL homology modeling. Arrows depict the TM3-4 and TM4b-4c loops (Arnold et al., 2006; Kiefer et al., 2009; Biasini et al., 2014).
