ABSTRACT

Bortezomib alone and in combination with other anticancer agents are extensively used for chemotherapeutic treatment of multiple myeloma (MM) patients and are being developed for treating other cancers. Bortezomib acts through multiple pathways, and in this study with ANBL-6 and RPMI 8226 MM cells we show that bortezomib inhibited growth and induced apoptosis and that this was accompanied by downregulation of specificity protein (Sp) 1, Sp3, and Sp4 transcription factors that are overexpressed in these cells. Similar results were observed in pancreatic and colon cancer cells. The functional importance of this pathway was confirmed by showing that individual knockdown of Sp1, Sp3, and Sp4 in MM cells inhibited cell growth and induced apoptosis, and that this correlates with the results of previous studies in pancreatic, colon, and other cancer cell lines. The mechanism of bortezomib-mediated downregulation of Sp transcription factors in MM was due to the induction of caspase-8 and upstream factors, including Fas-associated death domain. These results demonstrate that an important underlying mechanism of action of bortezomib was due to the activation of caspase-8–dependent downregulation of Sp1, Sp3, Sp4, and pro-oncogenic Sp-regulated genes.

Introduction

Multiple myeloma (MM) is a B-cell malignancy associated with terminally differentiated plasma cells that proliferate in the bone marrow, and complications from MM include bone marrow failure, renal disease, and osteolytic bone disease (Cook, 2008; Dimopoulos et al., 2015; Paiva et al., 2015; Anderson, 2016). It is estimated that 30,770 new cases of MM will be diagnosed in 2018 and 12,770 patients will die of this disease in the United States (Siegel et al., 2018). Among all cancers, the number of Food and Drug Administration approvals for new therapies are among the highest for MM (Anderson, 2016; Bates, 2016; Neri et al., 2016; Orlowski and Lonial, 2016), and this has contributed to the improvements in overall survival from this disease from 3 years in the 1960s to 8–10 years (Anderson, 2016). Among the most recent and prominent therapies for treating patients with MM include the class of proteasome inhibitors such as bortezomib (Velcade; Takeda Pharmaceuticals International Corporation, Cambridge, MA) and immunotherapies that are being developed for many cancers (Anderson, 2016; Bates, 2016; Neri et al., 2016; Orlowski and Lonial, 2016).

One of the major advances in the treatment of MM was the development and clinical applications of bortezomib, a proteasome inhibitor that is used extensively in MM chemotherapy (Hideshima et al., 2001, 2003; LeBlanc et al., 2002; Mitsiades et al., 2002; Richardson et al., 2005; San Miguel et al., 2008) and in drug combination therapies. Bortezomib and related analogs target the ubiquitin-proteasome pathway by interacting with N-terminal threonine residues in the active site of the proteasome catalytic region, thereby blocking the function of the 26S proteasome (Pandit and Gartel, 2011). Although bortezomib was initially characterized as a proteasome inhibitor, there is evidence that this agent induces anticancer activities in MM and other cancer cell lines through many other pathways, including the induction of reactive oxygen species (ROS), intracellular stress, and apoptosis (Laussmann et al., 2011; Lipchick et al., 2016; Xian et al., 2017). Treatment of MM cells and other cancer cell lines with bortezomib has also been linked to the downregulation of specificity protein (Sp) 1 transcription factor. For example, bortezomib induces microRNA-29b (miR-29b) in MM cells and acute myeloid leukemia cells, and this is associated with the downregulation of Sp1 and Sp1-regulated genes/responses (Liu et al., 2008; Amodio et al., 2012; Blum et al., 2012); in MM cells, miR-29b and Sp1 are part of feedback loop where decreased expression of Sp1 induces miR-29b (Amodio et al., 2012). Another study (Bat-Erdene et al., 2016) showed that bortezomib decreased the expression of Sp1 in MM cells, and this was accompanied by the decreased expression of Sp1-regulated survival factors IRF4 and cMyc.

Research in our laboratory has focused on Sp transcription factors as drug targets, and it has been demonstrated that Sp1, Sp3, and Sp4 are overexpressed in multiple cancer cell lines (Mertens-Talcott et al., 2007; Chadalapaka et al., 2012; Nair et al., 2013; Jutooru et al., 2014, 2015; Hedrick et al., 2015, 2017; Kasiappan et al., 2016; Karki et al., 2017; Safe et al., 2018), whereas levels of Sp2 and Sp5 were either low or variable and were not further investigated. RNA interference...
studies show that Sp1, Sp3, and Sp4 individually regulate cell proliferation, survival, and migration of cancer cells (Hedrick et al., 2016). Bortezomib is a widely used anticancer agent, and it is essential to understand its mechanism of action, particularly in MM, since insights into its mechanisms are important for designing drug combination therapies. The results of this study demonstrate that not only Sp1, but also Sp3 and Sp4 are highly expressed and exhibit pro-oncogenic activities in MM cells, as previously observed in other cancer cell lines. Moreover, bortezomib induces caspase-8–dependent downregulation of Sp1, Sp3, and Sp4 in MM cells, suggesting that an important mechanism of action of this drug is due to targeting the downregulation of Sp1, Sp3, and Sp4.

Materials and Methods

Cell Lines, Antibodies, and Reagents. The MM cell lines (ANBL-6 and RPMI 8226) were gifts from Robert Z. Orlowski (Department of Lymphoma and Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX). Panc1, L3.6P, and SW480 cells were purchased from American Type Culture Collection (Manassas, VA). ANBL-6 and RPMI 8226 cells were maintained at 37°C in the presence of 5% CO₂ in RPMI 1640 medium with 10% fetal bovine serum (FBS), and for ANBL-6 cells, interleukin-6 (1 ng/ml) was added. Similarly, Panc1, L3.6P, MiaPaCa2, and SW480 cells were grown and maintained at 37°C in the presence of 5% CO₂ in Dulbecco’s modified Eagle’s medium (DMEM/Ham’s F-12 medium supplemented with 10% FBS. DMEM, RPMI 1640 medium, FBS, formaldehyde, sodium orthovanadate, and trypsin were purchased from Sigma-Aldrich (St. Louis, MO). c-myc (cat. no. 9402s), survivin (cat. no. 2808s), cleaved polyADP-ribose polymerase (cPARP; cat. no. 9541T), cyclin D1 (cat. no. 2978s), phosho (p–)-Fas-associated death domain (FADD) (cat. no. 2781s), caspase-3 (cat. no. 9662s), caspase-8 (cat. no. 9746T), FADD (cat. no. 2782T), and cleaved caspase-8 (cat. no. 9496T) antibodies were obtained from Cell Signaling Technology (Boston, MA). Sp1 (cat. no. ab13370) antibody was purchased from Abcam (Cambridge, MA); Sp3 (cat. no. sc-644), Sp4 (cat. no. sc-645), epidermal growth factor receptor (EGFR) (cat. no. sc-373746), and bcl2 (cat. no. sc-7382) antibodies were obtained from Santa Cruz Biotechnology (Dallas, TX); and β-actin (cat. no. A5316) antibody from Sigma-Aldrich. Immobilon Western chemiluminescence reagents for Western blot imaging were purchased from Millipore (Billerica, MA), and bortezomib was purchased from LC Laboratories (Woburn, MA). The Apoptotic, Necrotic, and Healthy Cells Quantification Kit was purchased from Invitrogen (Grand Island, NY); and the XTT Cell Viability Kit was obtained from Cell Signaling Technology. Caspase-8 inhibitor (Z-IETD-FMK; cat. no. 9496T) and interleukin-6 (cat. no. 9661L), caspase-8 (cat. no. 9746T), FADD (cat. no. 2782T), caspase-3 (cat. no. 9662s), cleaved caspase-3 (cat. no. 9496T) reagents for Western blot imaging were purchased from Millipore (Billerica, MA), and bortezomib was purchased from LC Laboratories (Woburn, MA). The complexes used in the study are as follows:

- iNS-5: CGU ACG CGG AUA AUU UCAG A (nonspecific)
- siSp1: SASI_Hs02_0033289 [1] SASI_Hs01_00140198 [2]
- siSp3: SASI_Hs01_00211941 [3]
- siCaspase-8: SASI_Hs02_0031422 [1] SASI_Hs02_00314221 AS

The effects of knockdown were determined 72 hours after initial transfection.

Statistical Analysis. One-way analysis of variance and Dunnett’s test were used to determine the statistical significance between two groups. To confirm the reproducibility of the data, the experiments were performed at least three independent times, and the results are expressed as the mean ± S.D. P values <0.05 were considered to be statistically significant.

Results

Bortezomib Decreases Expression of Sp Transcription Factors in MM Cells and Other Cancer Cell Lines. In this study, we used human ANBL-6 and RPMI 8226 MM cell lines, and treatment with 1–20 nM bortezomib decreased the growth of both cell lines with significant growth inhibition observed at 1 nM bortezomib after treatment for
24 and 48 hours (Fig. 1, A and B). Bortezomib also induced Annexin V staining (apoptosis marker) in both cell lines (Fig. 1C; Supplemental Fig. 1A), and statistically significant induction was observed after treatment with 5–10 nM bortezomib. This concentration range also induced caspase-3 cleavage in ANBL-6 and RPMI 8226 cells (Fig. 1D). Previous studies have shown that Sp1 is expressed in MM cells and bortezomib decreased Sp1 levels, and the results in Fig. 1E confirms that bortezomib downregulated Sp1 in ANBL-6 and RPMI 8226 cells. However, it is also evident that Sp3 and Sp4 are highly expressed in both cell lines, and that bortezomib decreased the levels of Sp3 and Sp4 proteins; the effects were observed in cells after treatment with 1–5 nM bortezomib. 

Cyclin D1, survivin, and bcl-2 are typical Sp-regulated genes (Safe et al., 2018), and bortezomib decreased the levels of these proteins in MM cells.

Since bortezomib is being developed to treat multiple cancers, we next investigated the effects of this compound in Panc1 and L3.6pL pancreatic and SW480 colon cancer cell lines. Figure 2, A–C demonstrates that 5–100 nM bortezomib treatment for 24–48 hours decreased the growth of all three cell lines. Western blot analysis also showed that bortezomib induced caspase-3 cleavage in these cell lines (Fig. 2D). In addition, bortezomib also decreased the expression of Sp1, Sp3, and Sp4 in Panc1, L3.6pL, and SW480 cells, and levels of Sp-regulated cMyc and EGFR were also decreased (Fig. 2E). Previous studies have reported several other anticancer agents induce similar responses in these cell lines (Nair et al., 2013; Jutooru et al., 2014; Kasiappan et al., 2016; Safe et al., 2018).

RNA interference studies in Panc1, L3.6pL, and SW480 cells and other cancer cell lines show that the knockdown of Sp1, Sp3, and Sp4 individually and in combination resulted in growth inhibition and the induction of apoptosis (Hedrick et al., 2016). Therefore, ANBL-6 and RPMI 8226 cells were transfected with oligonucleotides that target Sp1 (iSp1), Sp3

Fig. 1. Bortezomib (Bort) inhibits MM cell growth and survival, and downregulates Sp1, Sp3, and Sp4. ANBL-6 cells (A), RPMI 8226 cells (B), and both cell lines (C) were treated with 1–20 nM bortezomib for 24 hours, and the effects on cell growth and Annexin V staining were determined as outlined in Materials and Methods. ANBL-6 and RPMI 8226 cells were treated with 1–20 nM bortezomib for 24 hours, and whole-cell lysates were analyzed for markers of apoptosis (D) and Sp transcription factors and Sp-regulated genes (E) by Western blots. (A–C) Results are expressed as the mean ± S.D. for at least three replicated experiments, and significant effects of treatment compared with solvent-treated controls are indicated (*P < 0.05). Both high–molecular weight (top) and low–molecular weight (bottom) forms of Sp3 are shown in all Western blots. Cas3, caspase-3.
(iSp3), Sp4 (iSp4), and their combination (iSp1/3/4), and the effects on Sp knockdown were determined by Western blots of whole-cell lysates (Fig. 3A). Knockdown of Sp1 decreased the expression of Sp1 and also Sp4 in both cell lines; knockdown of Sp3 decreased Sp3 and also Sp1 (ANBL-6 and RPMI 8226) and Sp4 (ANBL-6); and knockdown of Sp4 primarily decreased only the target protein. The specificity of Sp knockdown is cell context dependent (Hedrick et al., 2016), and their self-regulation is due, in part, to common GC-rich cis-elements in the 5'-promoter regions of Sp1, Sp3, and Sp4 genes (Nicolás...
et al., 2001; Song et al., 2001; Lou et al., 2005). Transfection of these oligonucleotides individually also decreased proliferation (Fig. 3B) and induced Annex V staining (Fig. 3C) in ANBL-6 and RPMI 8226 cells. Thus, Sp1, Sp3, and Sp4 individually regulate MM cell growth and survival, and the knockdown of one Sp transcription factor is not compensated by the other two; this has previously been observed in other cancer cell lines, including Panc1, L3.6pL, and SW480 cells (Hedrick et al., 2016). Thus, bortezomib-mediated downregulation of not only Sp1, but also Sp3 and Sp4 contributes to the effects of this compound on growth inhibition and induction of apoptosis.

Previous studies show that drug-induced downregulation of Sp transcription factors is due to the induction of proteolytic enzymes or phosphatases, or through the induction of ROS (Safe et al., 2018). Results illustrated in Fig. 4A demonstrate that the phosphatase inhibitor okadaic acid (OKA) did not affect bortezomib-induced Sp downregulation, whereas the caspase-8 inhibitor FMK-ZEITD but not Z-FA-FMK (nonspecific) inhibited degradation of Sp1, Sp3, and Sp4 in ANBL-6 and RPMI 8226 cells. Similar results were observed in L3.6pL and SW480 cells (Fig. 4B), and we did not observe any inhibitory effects by the caspase-3 inhibitor DEVD (Fig. 4, C and D). Bortezomib-induced downregulation of Sp1, Sp3, and Sp4 was not inhibited by the antioxidants GSH or NAC in ANBL-6 and RPMI 8226 cells (Fig. 4E) and L3.6pL and SW480 cells (Fig. 4F), and therefore was not ROS dependent; this was consistent with the failure of bortezomib to induce ROS in ANBL-6 and RPMI 8226 cells (Supplemental Fig. 2). Interestingly, previous studies have reported that bortezomib induces the activation of caspase-8 (Liu et al., 2007; Laussmann et al., 2011; Amodio et al., 2012; Bullenkamp et al., 2014; Bat-Erdene et al., 2016) and bortezomib-mediated Sp1 degradation is blocked by FMK-ZEITD (Bat-Erdene et al., 2016). A role for caspase-3–dependent cleavage of Sp1 has also been reported (Torabi et al., 2018). The inhibition of bortezomib-induced effects by FMK-ZEITD is consistent with the observed induction of caspase-8 in MM cells (ANBL-6 and RPMI 8226) (Fig. 5A) and the L3.6pL pancreatic and SW480 colon cancer cells (Fig. 5B). We also investigated possible upstream activators of caspase-8 and the extrinsic apoptosis pathway and observed that FADD was induced by bortezomib in MM cells (Fig. 5C), as previously observed in Hela cervical cancer cells (Laussmann et al., 2011). FADD was also induced in pancreatic and colon cancer cells (Fig. 5D). The role of caspase-8 in mediating bortezomib-induced Sp downregulation was confirmed in MM, SW480, and L3.6pL cells since treatment of the cell lines with
bortezomib plus an oligonucleotide-targeting caspase-8 blocked the downregulation of Sp1, Sp3, and Sp4 (Fig. 5E).

The role of bortezomib-induced caspase-8 on the effects of this compound on MM cell proliferation was determined in ANBL-6 and RPMI 8226 cells treated with FMK-ZEITD, Z-FA-FMK, and bortezomib alone and in combination. Bortezomib-mediated inhibition of MM cell proliferation was inhibited by FMK-ZEITD but not Z-FA-FMK (Fig. 6A), and similar results were observed for Annexin V staining (Fig. 6B; Supplemental Fig. 1B). Not surprisingly, the effects of FMK-ZEITD were more pronounced for the Annexin V assay. We also observed similar effects in L3.6pL and SW480 cells (Fig. 6, C and D), demonstrating that bortezomib-induced activation of caspase-8 plays an important role in mediating the growth inhibitory and proapoptotic effects of this compound in MM and other cancer cell lines.

We also examined the time course–dependent effects of bortezomib on FADD, caspase-8, Sp1, Sp3, and Sp4 expression in the MM cell lines. In ANBL-6 and RPMI 8226 cells, the loss of Sp proteins was observed after 2 or 4 hours; cleaved caspase-8 was induced within 1–2 hours and pFADD was enhanced after 2 hours, suggesting that, in addition to FADD, other
factors upstream from caspase-8 may also be activated by bortezomib (Fig. 7, A and B). Similar results were observed for L3.6pL and SW480 cells (B). Figure 7E summarizes a possible mechanism of bortezomib-induced downregulation of Sp1, Sp3, and Sp4, which involves caspase-8–dependent proteolysis. Western blots at early time points show some cleavage products (data not shown), and the cleavage sites and rates of Sp1, Sp3, and Sp4 degradation will be investigated in future studies. Current studies are investigating the mechanisms associated with bortezomib-dependent induction of FADD and other upstream factors that activate caspase-8.

**Discussion**

Bortezomib and related proteasome inhibitors are used in drug combination therapies for the treatment of MM and are being evaluated for the treatment of other tumors (Anderson, 2016; Bates, 2016; Neri et al., 2016; Orlowski and Lonial, 2016). Therefore, it is essential that the mechanism of action of
this compound be understood so that combination therapies can take advantage of mechanism-based drug-drug interactions. Bortezomib works through multiple pathways in MM and other cancer cells, and our initial hypothesis was that bortezomib induced ROS, which results in an ROS-dependent pathway resulting in the repression of Sp1, Sp3, and Sp4 mRNAs/proteins and pro-oncogenic Sp-regulated genes. This pathway has been worked out for several ROS-inducing anticancer agents including benzyl- and phenethylisothiocyanates, histone deacetylase inhibitors, piperlongumine, and penfluridol (Juturu et al., 2014; Hedrick et al., 2015, 2017; Kasiappan et al., 2016; Karki et al., 2017). The treatment of MM cells with bortezomib decreased Sp1 protein expression, as previously reported; however, this response was not affected by cotreatment with bortezomib plus GSH or NAC (Fig. 4E), and the effects of bortezomib appeared to be ROS independent (Supplemental Fig. 2).

Previous studies have identified a miR-29b–Sp1 loop where miR-29b targets Sp1 (3′-untranslated region) to decrease gene expression; however, our results show that bortezomib not
only decreased levels of Sp1 but also of Sp3 and Sp4 in MM cells and other cancer lines, suggesting that bortezomib may induce degradation pathways that simultaneously target all three Sp transcription factors. Individual knockdown of Sp1, Sp3, and Sp4 in lung, kidney, breast, pancreatic, colon, and rhabdomyosarcoma cancer cell lines results in decreased cell proliferation, survival, and migration/invasion and decreased expression of pro-oncogenic Sp-regulated genes, suggesting that Sp transcription factors are nononcogene addiction genes (Hedrick et al., 2016). Similar results were observed in MM cells (Fig. 3), and this indicates that not only Sp1, but also Sp3 and Sp4 play an important role in the growth and survival of MM cells. Moreover, among these three Sp transcription factors that target GC-rich cis-elements, the loss of one factor is not compensated by the other two in MM cells, and this is consistent with their differential regulation of gene expression previously demonstrated in pancreatic, colon, and other cancer cells (Hedrick et al., 2016).

Among those agents that inhibit drug-induced Sp down-regulation including antioxidants, proteasome inhibitors, phosphatase inhibitors (OKA), zinc ions, and caspase inhibitors (reviewed in Safe et al., 2018), only the caspase-8 inhibitor FMK-ZEITD inhibited bortezomib-induced downregulation of Sp1, Sp3, and Sp4 (Fig. 4). This observation is consistent with previous reports showing that bortezomib activates caspase-8 and the extrinsic pathway of apoptosis (Liu et al., 2007; Laussmann et al., 2011; Bullenkamp et al., 2014; Bat-Erdene et al., 2016), and one of those reports also shows that the inhibition of caspase-8 blocked bortezomib-induced cell death (Bullenkamp et al., 2014), as observed in this study (Fig. 5).

Previous studies showed that the nonsteroidal anti-inflammatory drug tolfenamic acid also induced the degradation of Sp1, Sp3, and Sp4 in SW480 colon cancer cells (Pathi et al., 2014), and this response was blocked in cells cotreated with tolfenamic acid plus the caspase-8 inhibitor FMK-ZEITD.
mechanisms mediating antimony inactivity of proteasome inhibitor PS-341.
