ABSTRACT

ATP-binding cassette (ABC) transporters such as ABCB1 (P-glycoprotein), ABCC1 (MRP1), and ABCG2 (BCRP) are well known for their role in rendering cancer cells resistant to chemotherapy. Additionally, recent research provided evidence that, along with other ABC transporters (ABCA1 and ABCA7), they might be cornerstones to tackle neurodegenerative diseases. Overcoming chemoresistance in cancer, understanding drug-drug interactions, and developing efficient and specific drugs that alter ABC transporter function are hindered by a lack of in vivo research models, which are fully predictive for humans. Hence, the humanization of ABC transporters in mice has become a major focus in pharmaceutical and neurodegenerative research. Here, we present a characterization of the first *Abcc1* humanized mouse line. To

preserve endogenous expression profiles, we chose to generate a knockin mouse model that leads to the expression of a chimeric protein that is fully human except for one amino acid. We found robust mRNA and protein expression within all major organs analyzed (brain, lung, spleen, and kidney). Furthermore, we demonstrate the functionality of the expressed human ABCC1 protein in brain and lungs using functional positron emission tomography imaging in vivo. Through the introduction of loxP sites, we additionally enabled this humanized mouse model for highly sophisticated studies involving cell type-specific transporter ablation. Based on our data, the presented mouse model appears to be a promising tool for the investigation of cell-specific ABCC1 function. It can provide a new basis for better translation of preclinical research.

The establishment of the mice was financially supported by Immugenetics AG (Rostock, Germany). The mice are available to researchers at nonprofit organizations without restrictions against a one-time contribution to help maintaining the strain. The work of J.P. was financed by Deutsche Forschungsgemeinschaft/Germany [Grants PA930/9 and PA930/12]; Wirtschaftsministerium Sachsen-Anhalt/Germany [Grant ZS/2016/05/78617]; the Leibniz Association, Leibniz-Wettbewerb [Grant SAW-2015-IPB-2]; Latvian Council of Science/Latvia [Grant lzp-2018/1-0275]; HelseSØ/Norway [Grants 2016062, 2019054, and 2019055]; Norsk Forskningsrådet/Norway [Grants 251290 (FRIMEDBIO) and 260786 (PROP-AD)]; and Horizon 2020/European Union [Grant 643417 PROP-AD]. The work of O.L. and T.W. was financed by the Austrian Science Fund [Grant I 1609-B24 (to O.L.)], and the Lower Austria Corporation for Research and Education [Grant LS14-008 (to T.W.)]. PROP-AD is a European Union Joint Programme–Neurodegenerative Disease Research (JPND) project. The project is supported through the following funding organizations under the aegis of JPND [www.jpnd.eu; (Academy of Finland [AKA] Grant 301228 (Finland), Bundesministerium für Bildung und Forschung [BMBF] Grant 01ED1605 (Germany), Chief Scientific Office of the Israeli Ministry [CSO-MOH] Grant 30000-12631 (Israel), Norges Forskningsråd/Norwegian Research Council [NFR] Grant 260786 (Norway), and Swedish Research Council [SRC] Grant 2015-06795 (Sweden)]. This project has received funding from the European Union's Horizon 2020 research and innovation program [Grant 643417 (JPco-fuND, co-funded initiative between JPND and the European Commission)].

Introduction

ATP-binding-cassette (ABC) transporters play a pivotal role in the protection of the human body against xenobiotics as mediators in signaling pathways and are crucial to certain metabolic processes (Theodoulou and Kerr, 2015). The best characterized ABC transporter is probably ABCB1 (P-glycoprotein). It is highly investigated because of its profound impact on the therapy outcome of many different types of cancer, as is ABCG2 (BCRP) (Noguchi et al., 2014; Wijaya et al., 2017). Both transporters also significantly contribute to the absorption, distribution, metabolism, and excretion of drugs (Giacomini et al., 2010). Due to mostly basolateral cellular localization, ABCC1 is relevant for the distribution of drugs in the body, but not for their absorption and excretion (Giacomini et al., 2010). Nevertheless, ABCC1 also plays a role in the chemoresistance of different cancers. For instance, high ABCC1 expression is a negative prognostic factor in cases of soft tissue sarcoma (Citti et al., 2012; Martin-Broto et al., 2014) and acute myeloid and lymphoblastic leukemia (van der Kolk et al., 2000; Winter et al., 2013; Liu et al., 2018). Furthermore, this correlation has been shown for neuroblastoma patients. However, it mainly arises through MYCN gene multiplication and its regulatory connection to ABCC1

(Haber et al., 2006; Alisi et al., 2013). ABCC1 was also found to be the most prominent multidrug resistance transporter in glioblastoma cells and glioblastoma stem-like cells, which are assumed to be the major reason for the high recurrence rate of glioblastomas (Huang et al., 2010; Peigné et al., 2011; Crowder et al., 2014; Torres et al., 2016). Accordingly, inhibition of ABCC1 was suggested to improve response to glioblastoma-directed chemotherapy (Peigné et al., 2011; Tivnan et al., 2015). Among the known substrates of ABCC1 are drugs such as vincristine and etoposide (used in glioblastoma therapy) (Tivnan et al., 2015), methotrexate (used in psoriasis and cancer treatment), citalopram (for the treatment of major depression), montelukast (an asthma medication), and anthracyclines (for the treatment of several different classes of cancer) (Smith et al., 2010; Giordano et al., 2012; Nabhan et al., 2015; Chihara et al., 2016; McGowan et al., 2017). However, it is important to note that ABCC1 is not the main treatment target or mechanism of resistance in many of these conditions. Moreover, a range of endogenously produced molecules such as leukotriene C₄ (Leier et al., 1994), 17 β -estradiol 17-(β -D-glucuronide) (Stride et al., 1997), sphingosine-1-phosphate (Cartwright et al., 2013), and cobalamin (vitamin B₁₂) (Beedholm-Ebsen et al., 2010), as well as glutathione, glucuronide, and sulfate conjugates (Müller et al., 1994; Jedlitschky et al., 1996), require ABCC1 for their extrusion and/or relocation. Furthermore, our own work provided evidence that ABCC1 function is of important relevance with regard to Alzheimer's disease (Krohn et al., 2011, 2015; Hofrichter et al., 2013), and in sustaining the homeostasis of neural stem and progenitor cells in healthy and diseased mouse brains (Schumacher et al., 2012; Pahnke et al., 2013). Recently, a family with clinical fronto-temporal dementia/degeneration, but autopsy-confirmed histologic Alzheimer's disease, has been discovered in the United States to have a germline mutation in the *ABCC1* gene (chromosome 16: 16216007 A > G, p.Y1189C) (unpublished data).

As is known for ABCB1 and ABCG2, the substrate specificity of the murine ABCC1 protein differs from that of its human ortholog. For example, Stride et al. (1997) have shown that both human and mouse ABCC1 transporters have similar affinities to leukotriene C₄, vinblastine, vincristine, and VP-16. However, the murine ABCC1 was found to be incapable of transporting any of the anthracyclines tested (doxorubicin, epirubicin, and daunorubicin) (Stride et al., 1997). In a mutagenesis study, the same group was later able to determine that a single amino acid (E1089, human protein) is important for conferring the anthracycline resistance (Zhang et al., 2001). Conversely, the reciprocal mutation Q1086E in the mouse ortholog led to only about 60% of the resistance level of the human ABCC1-expressing cell line (Zhang et al., 2001). Stride et al. (1997) also found that the endogenous metabolite 17 β -estradiol 17-(β -D-glucuronide) is efficiently transported by human ABCC1, but far less by the mouse ortholog.

In light of the known and further expected differences between human and mouse ABC transporter substrate specificities, the establishment of mouse models that express the human transporter instead of their endogenous ortholog is being pursued (Choo and Salphati, 2018). This

so-called humanization of mice holds the promise of bridging cross-species differences during preclinical drug development and increasing the clinical relevance of results obtained from mouse models of various diseases (Devoy et al., 2011).

Because of its impact on the outcome of various therapies, disease development, and the described differences between mouse and human ABCC1 protein substrate specificities, we sought to establish an *Abcc1* humanized mouse model. In the present work, we describe the generation and basic characterization of a mouse model that expresses the mouse-human chimeric *ABCC1* gene (>99.9% human) under the endogenous *Abcc1* promoter. We determined mRNA and protein expression levels in multiple organs and verified ABCC1 function in vivo using positron emission tomography (PET) imaging.

Materials and Methods

Generation of Humanized ABCC1 Mice (*hABCC1^{flx/flx}*)

Model design and generation was performed by and in collaboration with genOway (Lyon, France).

Targeting Vector Construct. Humanization of the murine *Abcc1* gene was performed by in-frame replacement of exon 2 with the human *ABCC1* coding sequence (CDS), devoid of the first exon, to keep it under control of the endogenous promoter. Downstream from the *hABCC1* CDS, a neomycin resistance cassette [flanked by flippase (Flp) recognition target sites for later Flp-mediated excision] was introduced to enable positive selection of clones (Fig. 1). Moreover, the CDS was flanked by loxP sites to allow Cre recombinase-mediated deletion. Since deletion of the human CDS would result in restoration of the murine *Abcc1* gene and protein expression (lacking only exon 2–encoded amino acids), additionally two point mutations in exon 3 of the murine gene were inserted. With these mutations, premature stop codons are present in each of the three possible reading frames.

Generation and Screening of Humanized ABCC1 Embryonic Stem Cell Clones. The linearized targeting vector with a size of 19 kilobase pairs was purified and used for electroporation of C57BL/6N embryonic stem (ES) cells according to genOway's standard electroporation procedure (5×10^6 ES cells in the presence of 40 μ g vector at 260 V and 500 μ F). Positive selection was initiated after 48 hours using 200 μ g/ml G418 (Sigma-Aldrich). The electroporation session resulted in 144 positive clones, which were amplified as duplicates in 96-well plates. One set of clones was frozen and stored at -80°C . The second set of clones was used for DNA preparation and screened for homolog recombinations. After initial polymerase chain reaction (PCR) screening for the homolog recombination event, amplicates of correct size were sequenced to confirm integrity of the transgene and the presence of the two point mutations in exon 3. Out of 11 ES cell clones picked for sequencing, nine clones were confirmed to be flawless. Southern blots further confirmed correct integration of the 3' and 5' ends of the vector in six of these clones.

Generation of Chimeric Mice and Breeding. To generate chimeric mice, recipient blastocysts were isolated from B6(Cg)-Tyr^{c-2J}/J mice. For injection into blastocysts, four ES cell clones were selected, which were reimplanted into pseudo-pregnant OF1 females. The B6(Cg)-Tyr^{c-2J}/J mice carry a mutation causing albinism but are otherwise genetically identical to C57BL/6J mice. This mutation allows easy monitoring of the degree of chimerism of the offspring generated by the combination of blastocysts from white-colored mice and ES cell clones from black-colored mice. Six males from three different clones with more than 50% chimerism were generated and used for breeding with C57BL/6J Flp deleter mice as

Abcc1 endogenous locus

Fig. 1. Targeting vector schematics and targeting strategy. Organization of the mouse *Abcc1* gene containing 28 exons (striped rectangles) is shown in the top row. Below, the targeted region encompassing exons 2 and 3 is magnified. The targeting construct was designed to replace exon 2 with the human *ABCC1* CDS (indicated by the gray lines). Long (upstream of exon 2) and short (downstream from exon 2) homology arms of the targeting vector are indicated as a black, solid line. They include loxP sites (blue triangles) and a neomycin-resistance cassette flanked by flippase recognition target (FRT) sequences. Newly introduced stop codons are indicated in exon 3.

soon as the animals reached sexual maturity. Breeding to Flp deleter mice ensured excision of the neomycin cassette as well as restoration of uniform black fur color. Only in chimeras from one ES cell clone germline was transmission observed, resulting in 12 F1 animals. Only two males were found to be lacking the neomycin resistance cassette. After positive reevaluation of transgene integration by southern blot, these males were bred to C57BL/6J females to establish the *hABCC1*^{flx/flx} mouse line. The *hABCC1*^{flx/flx} mice were registered in the Mouse Genome Informatics (MGI) database as B6.Cg-*Abcc1*^{tm1.1(ABCC1)Pahnk} (MGI: 6258225).

Genotyping

To guide and control breeding of the *hABCC1*^{flx/flx} and *hABCC1*^{-/-} animals, we designed a three-primer PCR that is able to distinguish all six possible genotypes [wt/wt; wt/fl; flx/flx; 0/fl; wt/0; and -/- (where wt denotes wild type)]. To do so, we exploited a 67-base pair inset introduced upstream of exon 2 that contains the 5'-loxP site and 35 additional nonendogenous nucleotides. Since this sequence is only present in *Abcc1*-modified mice, a two-primer PCR can distinguish between wild-type *Abcc1* and *hABCC1*^{flx/flx} alleles. A third (reverse) primer was placed downstream from the 3'-loxP side that produced a band only when the *hABCC1* CDS was excised. Primers used were N351_humC1_common (5'-cacatagtctctggcatttgg), N352_humC1_rc (5'-taagatggaggaggagctgtc), and N353_humC1_rcCre (5'-tctcaagttc-caggtcagcc). Band patterns produced by the different genotypes are summarized in Supplemental Table 1. PCR cycling was run as follows: 5 minutes at 95°C, 35 cycles of 45 seconds at 95°C, 60 seconds at 62°C, and 90 seconds at 72°C followed by 5 minutes at 72°C.

Additional Mouse Models

C57BL/6J wild-type and Cre-deleter (B6.C-Tg(CMV-cre)1Cg/J, JAX:006054) mice were purchased from The Jackson Laboratory (Bar Harbor, ME). To induce *hABCC1* knockout mice, we crossbred *hABCC1*^{flx/flx} mice to Cre-deleter mice. The resulting homozygous knockout mice are referred to as *hABCC1*^{-/-} mice and were registered as B6.Cg-*Abcc1*^{tm1.2Pahnk} (MGI: 6258262) in the MGI database. Conventional *Abcc1* knockout mice (FVB.129P2-*Abcc1*^{tm1Bor} N12; Taconic Farms, Denmark) (Wijnholds et al., 1997) were backcrossed to C57BL/6J mice for more than 12 generations to produce *Abcc1*^{-/-} mice within the same genomic background as *hABCC1*^{flx/flx} and *hABCC1*^{-/-} mice. All strains were bred and housed under specific and opportunistic pathogen free conditions at 21 ± 1°C, 12 hour/12 hour light/dark cycle with food (PM3; Special Diet Services) and acidified water ad libitum. All protocols involving the breeding and use of animals were approved by the Norwegian Food Safety (Mattilsynet) and the Austrian (Amt der Nösterreichischen Landesregierung) authorities. All study procedures were performed in accordance with the European Communities Council Directive of September 22, 2010 (Directive 2010/63/EU).

Tissue Preparation

Mice were sacrificed by cervical dislocation. After quick intracardial perfusion with 10 ml ice-cold PBS, one hemisphere of each brain was snap frozen in liquid nitrogen within 3 minutes after death. Additionally, samples of lung, spleen, and kidney were taken and snap frozen. All snap-frozen samples were stored at -80°C until use.

Quantitative PCR

Tissue samples of 100-days-old wild-type (four females, one male), *hABCC1*^{flx/flx} (four males) and *hABCC1*^{-/-} (four females, one male) mice were thawed on ice in RNeasy Lysis Buffer (Life Technologies) and homogenized using ceramic beads (SpeedMill PLUS; Analytischena AG, Germany). Total RNA of about 25 mg tissue was isolated using TRIzol (Life Technologies) and gene expression was analyzed employing EXPRESS One-Step qPCR SuperMIX (Life Technologies). Primer sets with respective TaqMan probes for mouse *Abcc1* (Mm00456156_m1), human *ABCC1* (Hs01561504_m1), and mouse *Actb* (Mm00607939_s1) genes were purchased from Thermo Fisher Scientific Inc. TaqMan assays are sets of primers, and a probe was validated for similar amplification efficiencies between different assays to ensure comparability. VIC (2'-chloro-7'-phenyl-1,4-dichloro-6-carboxy-fluorescein)-labeled *Actb* assays were run together with FAM (6-fluorescein amidite)-labeled *Abcc1* and *ABCC1* assays, respectively, in the same tubes to allow normalization of gene expression and calculation of $\Delta\Delta C_t$ values. All samples were tested with each TaqMan assay, including a nontemplate control. Reactions were performed according to the manufacturer's instructions with a final volume of 20 μ l and 75 ng of RNA. PCR amplification was performed using an AriaMX (Agilent Technologies), in which the conditions were 15 minutes at 50°C and 2 minutes at 95°C, followed by 40 cycles of 15 seconds at 95°C and 1 minute at 60°C.

Western Blot

Brain hemispheres of 100-days-old, wild-type (five females, six males), *hABCC1*^{flx/flx} (six females, five males) and *hABCC1*^{-/-} (six females, five males) mice were thawed on ice in RNeasy Lysis Buffer (Life Technologies) and choroid plexuses (CPs) were separated from the lateral ventricle using a preparative microscope. Each CP was put into 20 μ l of membrane protein lysis buffer [100 mM Tris (pH 8), 20 mM EDTA, 140 mM NaCl, 5% SDS, and protease inhibitors (cOmplete mini tablets; Roche)] and incubated for 1 hour at 50°C with occasional up-and-down pipetting. The remaining brain tissue as well as spleen, lung, and kidney samples were bead homogenized. About 25 mg of homogenate was taken for protein extraction using lysis buffer A [100 mM Tris (pH 7.4), 150 mM NaCl, 0.1% TritonX-100, DNase I, and protease inhibitors (cOmplete mini tablets; Roche)]. Samples were again submitted to bead homogenization and incubated for 15 minutes at room temperature before centrifugation at 4°C.

(13,000 rpm, 90 minutes). The pellets were resuspended in membrane protein lysis buffer and samples were incubated at 50°C for 1 hour before another round of centrifugation (room temperature, 13,000 rpm, 30 minutes). Supernatants were collected and subjected to protein concentration determination using a BCA Assay Kit (Pierce, ThermoFisher Scientific). For western blotting, samples were prepared with Laemmli buffer and subjected to gel electrophoresis using a 7.5% TGX self-casted gel matrix (Bio-Rad, Germany) and 60 µg protein per lane. In the case of CP samples, one-half of the available volume per sample (about 13 µl) was used per lane without determination of protein concentration due to the limited sample volume. Proteins were blotted onto 0.22 µm polyvinylidene fluoride membranes using a Trans-Blot Turbo system (Bio-Rad) and membranes were blocked with 1.5% nonfat dry milk in PBS/0.01% Tween 20 for 1 hour at room temperature. For protein detection, anti-ABCC1 antibody MRPr1 (1:400; Abcam), QCRL-1 (1:100; SantaCruz), and IU2H10 (1:100; Abcam) were used and incubated overnight at 4°C. Anti-ATP1A2 antibody [EPR11896(B)] (1:2000; Abcam) was used to assess amounts of NaCl-ATPase serving as an endogenous control. Secondary antibodies used for detection were horseradish peroxidase-conjugated, anti-rat (1:10,000; Jackson ImmunoResearch), three different anti-mouse antibodies to exclude secondary antibody-related detection issues [1:1000 (SantaCruz), 1:2000 (Novus Biologicals), and 1:5000 (Bethyl Laboratories)], and anti-rabbit (1:10,000; Jackson ImmunoResearch) antibodies, incubated for 1 hour at room temperature in PBS/0.01% Tween 20. After washing, Clarity-plus (Bio-Rad) electrochemiluminescence detection reagent was distributed over the polyvinylidene fluoride membranes and light signals were detected using the Octopplus QPLEX system (DyeAGNOSTICS, Germany). Signal analysis was performed using Image Studio Lite (LI-COR) and Microsoft Excel (Office 365).

Positron Emission Tomography Imaging

Imaging experiments were performed under isoflurane anesthesia. Animals (all females) were warmed throughout the experiment and body temperature and respiratory rate were constantly monitored. Mice were placed in a custom-made imaging chamber and the lateral tail vein was cannulated for intravenous administration. A microPET Focus220 scanner (Siemens Medical Solutions, Knoxville, TN) was used for PET imaging. Mice were injected intraperitoneally under anesthesia 30 minutes before the start of the PET scan either with vehicle solution (PBS; wild-type: $n = 6$, $hABCC1^{flx/flx}$: $n = 5$, $hABCC1^{-/-}$: $n = 4$, $Abcc1^{-/-}$: $n = 6$), or with MK571 (5-(3-(2-(7-Chloroquinolin-2-yl)ethenyl)phenyl)-8-dimethylcarbamyl-4,6-dithiaoctanoic acid) (Chemical Abstracts Service Number: 115103-85-0, 300 mg/kg; $hABCC1^{flx/flx}$: $n = 3$, wild-type: $n = 7$). Subsequently, 6-bromo-7- ^{11}C methylpurine (32.85 ± 7.34 MBq; 0.1 ml; 1.26 ± 14.80 nmol), which had been synthesized as described previously (Zoufal et al., 2019), was administered as an intravenous bolus via the lateral tail vein and a 90-minute dynamic PET scan was initiated at the start of radiotracer injection (timing window 6 nanoseconds; energy window of 250–750 keV).

The PET data were sorted into 25 frames with a duration increasing from 5 seconds to 20 minutes. PET images were reconstructed using Fourier rebinning of the three-dimensional sinograms followed by a two-dimensional filtered backprojection with a ramp filter giving a voxel size of $0.4 \times 0.4 \times 0.796$ mm³. Using AMIDE software (Loening and Gambhir, 2003), whole brain and right lung were manually outlined on the PET images to derive concentration-time curves expressed in units of standardized uptake value [standardized uptake value = (radioactivity per gram/injected radioactivity) \times body weight]. From the log-transformed concentration-time curves, the elimination slope of radioactivity washout from tissue [$k_{\text{elimination, brain}}$ or $k_{\text{elimination, lung}}$ (hour⁻¹)] was determined by linear regression analysis of data from 17.5 to 80 minutes after radiotracer injection (Zoufal et al., 2019).

Statistics

This study is exploratory in nature. Thus, all *P* values are descriptive only. Data were analyzed using Microsoft Excel 365 and GraphPad Prism 8.0 using the statistical tests indicated in the figure legends. All reported values are mean and the error bars indicate S.D.

Results

Design and Generation of $hABCC1^{flx/flx}$ Mice. Earlier publications indicate that promoter elements driving *Abcc1* expression in mice and rats are primarily located from position –27 base pairs and upstream (relative to the transcription start site) (Kurz et al., 2001; Muredda et al., 2003). However, more recent data from DNase sequencing and assay for transposase-accessible chromatin using sequencing experiments indicate regulatory relevance of the first exon and segments within the first intron around +10 and +16 kilobase pairs (ENCODE data sets ENCSR791AJY and ENCSR310MLB) (Supplemental Fig. 1). Furthermore, in-house analysis performed by genOway indicated DNase I protected sites and transcription factor binding sites in the 5' region of the *Abcc1* gene (Fig. 2).

In order to conserve these structures and avoid dysfunctional integration, as in the case of *Abcb1* humanized mice (Krohn et al., 2018), we decided to introduce the human *ABCC1* CDS in-frame into mouse exon 2, which is devoid of potential regulatory elements. We thereby generated a chimeric mouse/human *ABCC1* gene (Fig. 1). However, the first exon of both genes encodes 16 amino acids with only one amino acid being different (human: 1MALRG FCSAD GSDPL W16; mouse: 1MALRS FCSAD GSDPL W16). This strategy can be expected to result in some reexpression of *Abcc1* mRNA after recombination of the $hABCC1^{flx/flx}$ locus via Cre recombinase. Since the 5'-untranslated region and exon 1 are left untouched, transcription of the recombined gene will still be initiated, producing an mRNA lacking exon 2 ($\Delta\text{ex2-}Abcc1$). Although not recognized by the RNA polymerase, the additional stop codons we introduced in exon 3 should effectively terminate translation of this $\Delta\text{ex2-}Abcc1$ mRNA into proteins.

ABCC1 Expression. To assess the functionality of the new mouse lines, we determined mRNA and protein expression of murine *Abcc1* and human *ABCC1* in 100-days-old, wild-type, $hABCC1^{flx/flx}$ and $hABCC1^{-/-}$ mice. As expected, the TaqMan assay for human *ABCC1* mRNA neither generated signals in wild-type mice nor in $hABCC1^{-/-}$ mice, indicating the species specificity of the assay, and more importantly successful *ABCC1* knockout in $hABCC1^{-/-}$ mice (Supplemental Fig. 1). In $hABCC1^{flx/flx}$ mice, *ABCC1* mRNA was expressed in the brain, but at significantly lower levels than wild-type mRNA ($P = 0.0005$) while significantly stronger expression was found in lung tissues ($P < 0.0001$). However, murine *Abcc1* mRNA was hardly detectable in brain ($P = 0.0003$) and not detectable in the lungs of $hABCC1^{flx/flx}$ animals (Supplemental Fig. 1). Nevertheless, mRNA is not a reliable predictor of protein abundance or function (Pascal et al., 2008; de Sousa Abreu et al., 2009; Maier et al., 2009; Vogel and Marcotte, 2012).

Hence, we sought to determine ABCC1 protein expression in the newly developed mouse strains. The hourABCC1 protein abundance was determined by western blotting of whole brain homogenates from $hABCC1^{flx/flx}$ mice and revealed

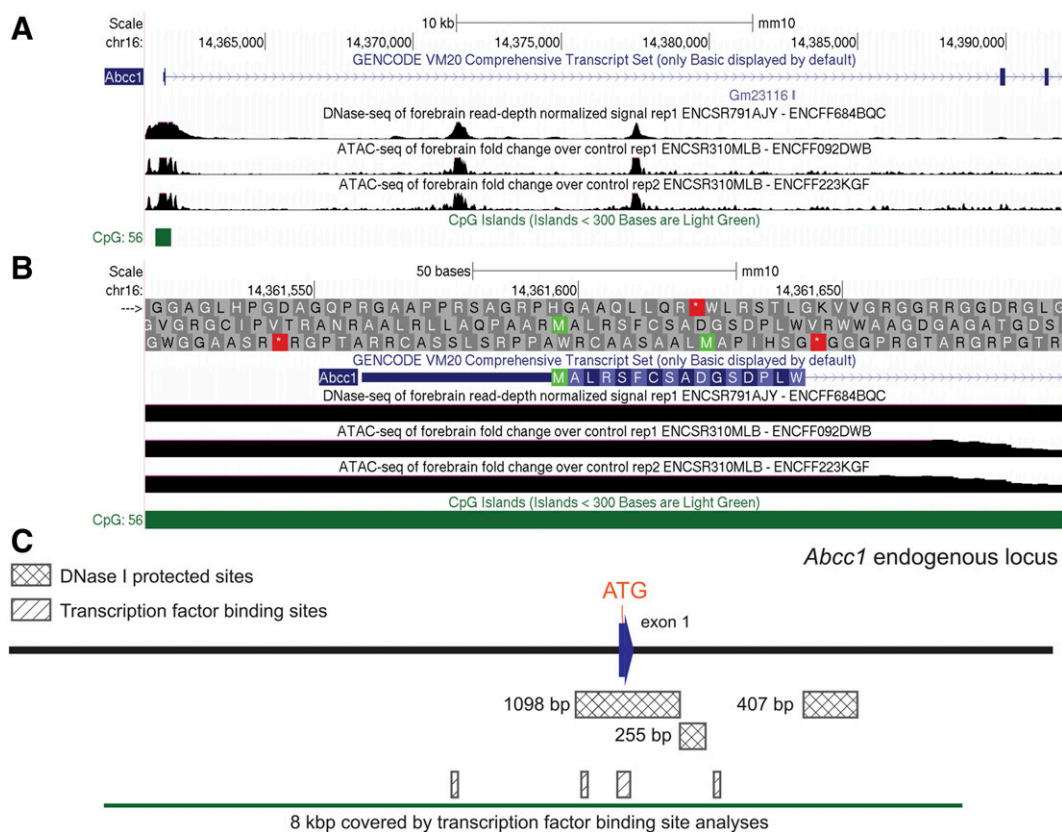

Fig. 2. Schematic overview of potential regulatory elements. Overview of DNase sequencing (DNase-seq) and assay for transposase-accessible chromatin using sequencing (ATAC-seq) data as well as location of CpG islands in the region within the first three exons [(A), blue boxes] of the *Abcc1* gene. In (B) a zoom into exon 1 is depicted. Pictures have been generated using the University of California, Santa Cruz, genome browser (genome.ucsc.edu). (C) Three DNase I protected sites and four conserved transcription factor-binding sites were identified in the vicinity and within exon 1 of *Abcc1* in an in-house analysis by genOway. Signals from all analyses indicate relevance of exon 1 and potentially intron 1 for regulation of *Abcc1* gene expression. In contrast, no such indicators are found around exons 2 and 3.

about 60% higher ABCC1 abundance ($P = 0.0002$) than in wild-type mouse brains (Fig. 3, A and C). In lung tissue, we found robust ABCC1 expression in *hABCC1^{flx/flx}* mice that was comparable to the expression in wild-type mice (Fig. 3, B and C). In both tissues, no detectable amounts of ABCC1 were found in *hABCC1^{-/-}* animals, indicating that the introduced stop codons are recognized by the translation machinery and interrupt the expression of any residual *Abcc1* gene product (Fig. 3). The same pattern of expression was found in western blots of kidney and spleen (Supplemental Fig. 2). We also analyzed single CPs from lateral ventricles, because the CP is the primary location of ABCC1 expression in the brain. Since determination of the protein concentration was not possible with such minute amounts of tissue and the extraction of the whole CP was not successful in all cases, the amounts of protein per lane varied substantially. Nevertheless, the signals indicated similar relative expression between the groups as was found in the other organs (Supplemental Fig. 2). To account for a likely higher binding affinity to human than mouse ABCC1 proteins (Hipfner et al., 1998) of the used MRPr1 antibody clone, we sought to use an antibody that recognizes a common epitope. The antibody clone IU2H10 was found to bind to amino acids 8–17 and should thus show the same affinity in both species (Chen et al., 2002). Unexpectedly, using this antibody did not result in detection of any band, regardless of the protocol used (data not shown). To further verify that only *hABCC1*

proteins are expressed in *hABCC1^{flx/flx}* mice, we used the QCRL-1 antibody clone (Hipfner et al., 1998) which is reported to not recognize mouse ABCC1. However, in our hands this antibody recognized an unknown protein of about the same size as ABCC1. As illustrated in Supplemental Fig. 3, all samples, including wild-type brains, show the same band pattern. As an additional control, we also blotted samples prepared from the well-characterized conventional *Abcc1^{-/-}* mice (Wijnholds et al., 1997), which also showed positive staining (Supplemental Fig. 3). Hence, using these antibodies did not yield any further results.

Positron Emission Tomography Imaging. The most important physiologic readout of any transgenic model is protein function. We used PET together with 6-bromo-7- $^{[11]C}$ methylpurine to measure ABCC1 transport activity in vivo. After intravenous injection, 6-bromo-7- $^{[11]C}$ methylpurine is distributed throughout the body, presumably by passive diffusion, and conjugated to glutathione within the cells by glutathione-S-transferases. The resulting metabolite *S*-(6-(7- $^{[11]C}$ methylpurinyl))glutathione is eliminated from tissue by ABCC1. 6-Bromo-7- $^{[11]C}$ methylpurine has been used before to measure ABCC1 transport activity in the brain and lungs of mice (Okamura et al., 2009, 2013).

By means of 6-bromo-7- $^{[11]C}$ methylpurine PET we compared ABCC1 transport activity in wild-type, *hABCC1^{flx/flx}*, *hABCC1^{-/-}*, and *Abcc1^{-/-}* mice to verify transporter functionality in the humanized mouse model. To further assess

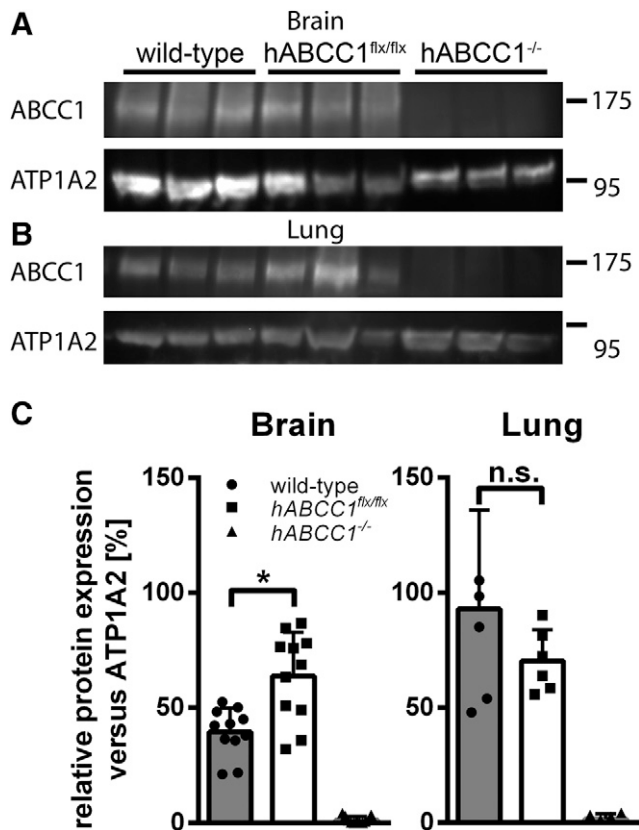

Fig. 3. Protein expression analysis. Representative western blots (A and B) and quantitative analyses for ABCC1 protein expression (C) are shown for brain and lung tissue, respectively. Without having knowledge about the affinities of the MRP1 antibody toward the human ABCC1 and mouse ABCC1 epitopes, respectively (differs at epitope position 1), ABCC1 protein expression in *hABCC1^{flx/flx}* brains ($n = 6$ females/5 males, white bar) appears significantly more abundant than in wild-type brains ($n = 5$ females/6 males, gray bar) (A and C). In lung tissue, no significant difference between wild-type mice ($n = 2$ females/3 males, gray bar) and *hABCC1^{flx/flx}* mice ($n = 4$ females/2 males, white bar) was detected (B and C). No significant expression of ABCC1 protein could be detected in *hABCC1^{-/-}* brains ($n = 6$ females/5 males) and lungs ($n = 2$ females/3 males) (#). ATP1A2 raw signal values are reported in Supplemental Table 3. Within each organ, one-way ANOVA of wild-type ABCC1 expression vs. all other groups was used, followed by Dunnett's correction for multiple comparisons. n.s., not significant. * $P < 0.05$; error bars = S.D.

transporter function we also acquired 6-bromo-7- $^{[11]C}$ -methylpurine PET scans in wild-type and *hABCC1^{flx/flx}* mice after pretreatment with the ABCC1 inhibitor MK571 (300 mg/kg, i.p.). In Fig. 4, representative PET images of all groups are depicted. No visual differences in radioactivity distribution to the brains and lungs could be observed between *hABCC1^{flx/flx}* and wild-type mice. In both *hABCC1^{-/-}* and *Abcc1^{-/-}* mice radioactivity uptake in the brain and lungs was higher than in *hABCC1^{flx/flx}* and wild-type mice. After MK571 pretreatment, radioactivity uptake in brain and lungs of *hABCC1^{flx/flx}* and wild-type mice was increased relative to vehicle-treated animals (Fig. 4). Concentration-time curves of radioactivity in the brain and lungs of all investigated mouse groups are shown in Fig. 5, A–D. As an outcome parameter of ABCC1 function, we determined the slope of radioactivity elimination from tissue [$k_{\text{elimination, brain}}$ and $k_{\text{elimination, lung}}$ (hour^{-1})] (Fig. 5, E and F). The $k_{\text{elimination, brain}}$ value of *hABCC1^{flx/flx}* mice exceeded that of wild-type mice by 43% (*hABCC1^{flx/flx}*: $1.96 \pm 0.1 \text{ hour}^{-1}$;

wild type: $1.37 \pm 0.27 \text{ hour}^{-1}$), while *hABCC1^{-/-}* and *Abcc1^{-/-}* mice were characterized by an almost complete loss of radioactivity washout (*ABCC1^{-/-}*: $0.18 \pm 0.01 \text{ hour}^{-1}$; *Abcc1^{-/-}*: $0.15 \pm 0.01 \text{ hour}^{-1}$) (Fig. 5E). The $k_{\text{elimination, lung}}$ value was not significantly different between wild-type and *hABCC1^{flx/flx}* mice with a tendency for higher values in *hABCC1^{flx/flx}* mice (*hABCC1^{flx/flx}*: $1.77 \pm 0.17 \text{ hour}^{-1}$; wild type: $1.52 \pm 0.1 \text{ hour}^{-1}$) (Fig. 5F), while *hABCC1^{-/-}* and *Abcc1^{-/-}* mice were characterized by a virtual lack of radioactivity washout (*hABCC1^{-/-}*: $0.22 \pm 0.02 \text{ hour}^{-1}$; *Abcc1^{-/-}*: $0.26 \pm 0.06 \text{ hour}^{-1}$) (Fig. 5F). Pretreatment with MK571 significantly reduced $k_{\text{elimination, brain}}$ and $k_{\text{elimination, lung}}$ values in both *hABCC1^{flx/flx}* and wild-type mice (Fig. 5, E and F).

Discussion

The ABCC1 protein has been described as a multitasking transporter by Cole (2014). Considering its diverse functions and diversity of substrates, this is certainly a most appropriate description. In the study presented here, we have engineered, to the best of our knowledge, the first mouse model that expresses the human ABCC1 transporter under the endogenous mouse promoter. An optimal humanized mouse strain would be characterized by three major properties: 1) the lack of expression of the replaced protein, 2) abundance and activity of the human protein at levels that are similar to the eradicated endogenous one, and 3) a tissue distribution of the human protein that resembles the former expression pattern of the endogenous protein. As can be seen in previous *Abcb1a/b* humanization attempts, careful examination of gene and promoter structures of the endogenous gene is essential to achieve these properties. Previously, Sadiq et al. (2015) published the characterization of an *Abcb1a/b* humanized mouse line developed by Taconic (Cologne, Germany). Their report clearly showed that this mouse model was not functional in relation to human ABCB1 expression and function. In a study published in 2018 by our group, we characterized another *Abcb1a/b* humanized mouse line, developed by genOway, which again showed no significant hABCB1 protein expression (Krohn et al., 2018). Very recently, Yamasaki et al. (2018) published results of the yet last *Abcb1a/b* humanization attempt. They produced a mouse artificial chromosome containing the full 210-kilobase human genomic *ABCB1* locus and generated transchromosomal mice. Despite lacking expression in intestinal epithelia, their analyses indicated functional expression of human ABCB1 at the blood-brain barrier (Yamasaki et al., 2018).

To reduce the risk of deteriorating the *Abcc1* promoter, we decided to pursue a strategy that leads to the expression of a chimeric gene. The chimerism is restricted to the first exon of the gene and results in the difference of a single amino acid at position 5 (G5S). We are not aware of any indication that the very N-terminal amino acids of ABCC1, nor any other ABC transporter, are of relevance to its function or substrate specificity. The first glycosylation site has been described at position N19 by Hipfner et al. (1997). In our hands, the ABCC1 protein bands have an observed size of about 175 kDa, although mouse and human ABCC1 have a molecular weight of about 190 kDa, which could hint to a lack of glycosylation of the protein. However, this inconsistency is most likely a technical anomaly because the size of

Fig. 4. PET imaging of brain ABCC1 transport activity. Representative coronal PET images (0–90 minutes) of *hABCC1*^{flx/flx}, wild-type, *hABCC1*^{-/-}, and *Abcc1*^{-/-} mice pretreated with vehicle or MK571 (300 mg/kg, i.p.) 30 minutes before the PET scan. Anatomic regions are labeled with arrows: B denotes brain and L denotes right lung. All images are scaled to the same intensity [0–3 standardized uptake value (SUV)].

detected ABCC1 in *hABCC1*^{flx/flx} mice is the same as that in wild-type mice, excluding differences in the translation or post-translational processing of both variants. In a cysteine substitution study, Leslie et al. (2003) found that only a C43S substitution led to a change in arsenide and vincristine resistance, but no other cysteine exchange within the first 210 amino acids. Finally, deletion of the N-terminus up to amino acid 64 did not alter leukotriene C₄ transport kinetics in a mutation study by Gao et al. (1998). Hence, we assume that the ABCC1 protein expressed by this *hABCC1*^{flx/flx} mouse line displays transport characteristics identical to fully human ABCC1.

Our mRNA expression analyses revealed substantial differences between wild-type *Abcc1* and *ABCC1* gene transcription in the brain and lungs. In the brain, *ABCC1* expression was significantly lower than wild-type *Abcc1* expression, whereas in lungs *ABCC1* mRNA levels were much higher than in wild-type mice. Interestingly, we found marginal restoration of *Abcc1* transcription in *hABCC1*^{-/-} brains, while it remained undetectable in lung tissue. Because we were aware that *Abcc1* expression could be restored after Cre recombination, we introduced additional stop codons into exon 3 to prevent mRNA translation and expression of a shortened mABCC1 protein. However, the differential effects seen in both tissues might hint toward differing promoter structures being used for *Abcc1* transcription in brain versus lung tissue. Since mRNA expression levels show a generally poor correlation with protein expression, mRNA expression analyses alone can be rather misleading (Pascal et al., 2008; de Sousa Abreu et al., 2009; Maier et al., 2009; Vogel and Marcotte, 2012).

Hence, we employed western blotting to verify protein expression in brain and lung tissues as well as in spleen, kidney, and CP. In contrast to the mRNA results, immunoblotting data revealed protein expression levels in *hABCC1*^{flx/flx} mice that were mostly similar to wild-type animals. However, in *hABCC1*^{flx/flx} brain tissue the ABCC1 expression was higher than in wild-type brains despite lower *ABCC1* mRNA expression in *hABCC1*^{flx/flx} mice. It should be noted that currently no commercially available anti-ABCC1 antibody can differentiate between mABCC1 and hABCC1 proteins. The used MRPr1 antibody clone recognizes a common epitope between G238 and E247 (human numbering). However, in mABCC1 a serine is found

at position 238 instead of a glycine, likely leading to the lower affinity of the MRPr1 antibody to the mABCC1 protein. It is likely that hABCC1 expression determined using this antibody overestimates the actual protein expression. To account for this difference and further prove the absence of any mABCC1 protein in *hABCC1*^{flx/flx} mice, we intended to use the IU2H10 and QCRL-1 antibodies, respectively. Regrettably, despite using different protocols and production batches, none of these antibodies yielded further insights. In our mouse brain samples, the IU2H10 antibody did not give any signal at all and the QCRL-1 antibody bound to an unknown protein even in the extensively used and characterized conventional *Abcc1*^{-/-} mice developed by Wijnholds et al. (1997). Nevertheless, our data generated from *hABCC1*^{-/-} mice using the MRPr1 antibody clearly indicate that after Cre recombination neither human nor mouse ABCC1 proteins are expressed. Although highly unlikely, translation of *Abcc1* mRNA expressed in *hABCC1*^{flx/flx} and *hABCC1*^{-/-} mice could be initiated within exon 8 (first possible in-frame ATG codon after exon 3 producing a protein not detected by MRPr1), and thus generate a rudimental mABCC1 protein not detectable with the MRPr1 antibody. However, earlier studies have shown that such shortened ABCC1 proteins (the longest possible protein here would be devoid of the first 327 amino acids) lack proper sorting to the plasma membrane and are dysfunctional (Bakos et al., 1998, 2000; Westlake et al., 2005; Yang et al., 2007). To prove functional ABCC1 expression in *hABCC1*^{flx/flx} mice, as well as the lack thereof in *hABCC1*^{-/-} mice, we used in vivo PET imaging.

6-bromo-7-[¹¹C]methylpurine has been introduced as a PET tracer to measure ABCC1 transport activity in the brain and lungs of mice (Okamura et al., 2009, 2013). In the brain, 6-bromo-7-[¹¹C]methylpurine is converted in parenchymal cells (e.g., astrocytes) by glutathione-*S*-transferases into its glutathione conjugate *S*-(6-(7-[¹¹C]methylpurinyl))-glutathione. The glutathione conjugate is then effluxed from parenchymal cells by ABCC1 followed by clearance across the blood-brain barrier by other anionic transporters (SLC22A8 and ABCC4) (Okamura et al., 2009, 2018). Previous work has shown that *Abcc1*^{-/-} mice possess an approximately 9-fold reduced *k*_{elimination, brain} value compared with wild-type mice, supporting that transport by mABCC1 is the rate-limiting step in the elimination of 6-bromo-7-[¹¹C]methylpurine-derived

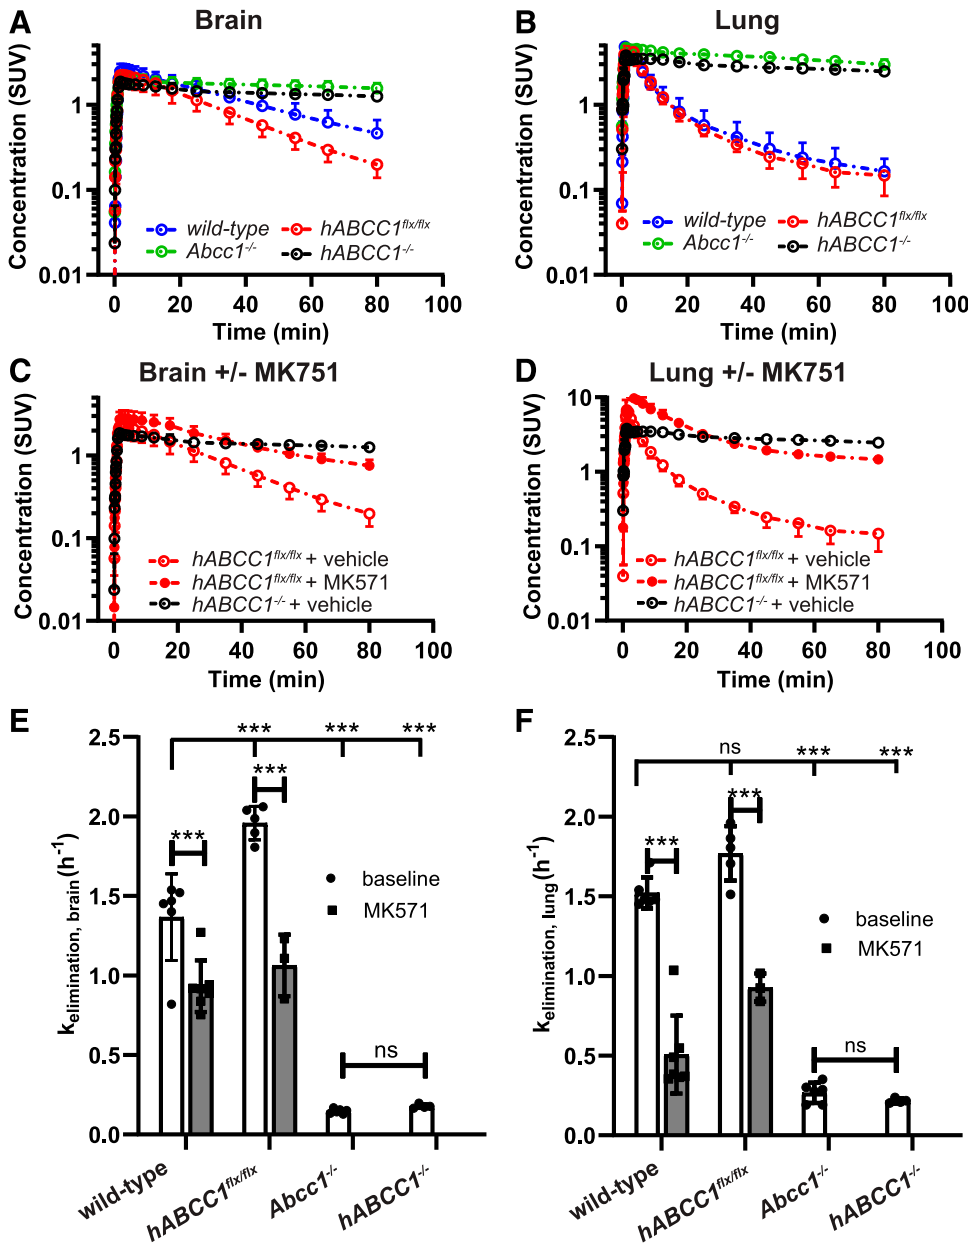

Fig. 5. Quantification of brain and lung PET imaging. Concentration-time curves (mean standardized uptake value \pm S.D.) in brain (A) and right lung (B) of wild-type ($n = 6$, females), *hABCC1^{flx/flx}* ($n = 5$, females), *Abcc1^{-/-}* ($n = 6$, females), and *hABCC1^{-/-}* ($n = 4$, females) mice. Concentration-time curves in brain (C) and right lung (D) of *hABCC1^{flx/flx}* mice pretreated with vehicle or MK571 (300 mg/kg, i.p.) 30 minutes before PET (for comparison, curves in *hABCC1^{-/-}* are also shown). The $k_{\text{elimination}}$ values (mean $h^{-1} \pm$ S.D.) of radioactivity from brain (E) and right lung (F) of wild-type, *hABCC1^{flx/flx}*, *Abcc1^{-/-}*, and *ABCC1^{-/-}* mice with vehicle (white bars) or MK571 (gray bars) pretreatment. *** $P < 0.001$, one-way ANOVA followed by Tukey's multiple comparisons test. n.s., not significant. Error bars = S.D.

radioactivity from the mouse brain (Okamura et al., 2009; Zoufal et al., 2019). In addition, in vitro transport experiments have demonstrated that the glutathione conjugate of 6-bromo-7-methylpurine is also a substrate of hABCC1 (Okamura et al., 2007). In the lungs, ABCC1 is expressed in the basolateral membrane of pulmonary epithelial cell types (airway epithelial cells and alveolar type 2 and 1 cells) (Nickel et al., 2016). 6-Bromo-7- ^{11}C methylpurine PET revealed pronounced reductions in the $k_{\text{elimination, lung}}$ value in *Abcc1^{-/-}* mice versus wild-type mice (Okamura et al., 2013; Zoufal et al., 2019). These great reductions in $k_{\text{elimination, brain}}$ and $k_{\text{elimination, lung}}$ values in *Abcc1^{-/-}* versus wild-type mice indicated absence of transporter redundancy for radiolabeled glutathione conjugate efflux in the cell membranes of brain parenchymal and pulmonary epithelial cells. Hence, the most likely explanation for similar clearance kinetics of radioactivity from brain and lungs in *hABCC1^{flx/flx}* mice compared with wild-type mice

(Fig. 5, A–D) is the replacement of endogenous mABCC1 transport activity by hABCC1 transport activity. In *hABCC1^{flx/flx}* lungs, the radioactivity clearance kinetics results were nearly identical to those in wild-type mice (Fig. 5, B and F). In the brain, the radioactivity elimination was significantly higher in *hABCC1^{flx/flx}* animals when compared with wild-type mouse brains (Fig. 5, A and E). These PET imaging data correlate well with the determined protein expression levels (Fig. 3). Furthermore, our results clearly show that *hABCC1^{-/-}* mice are indeed fully deficient of ABCC1 transport activity. Interestingly, initial uptake of radioactivity in brain and lungs appeared to be lower in *hABCC1^{-/-}* mice compared with *hABCC1^{flx/flx}* mice (Fig. 5, C and D). The initial concentrations of radioactivity in the brain and lungs reflected unconverted 6-bromo-7- ^{11}C methylpurine, which is believed to distribute to tissues via passive diffusion. One possible explanation for the observed differences in initial tissue uptake of radioactivity could be differences in organ blood flow.

As expected, we also did not observe any overt phenotypic difference between *hABCC1^{flx/flx}*, *hABCC1^{-/-}*, and wild-type C57BL/6J mice while breeding or during daily handling (Wijnholds et al., 1997). In combination with the large variety of commercially available organ and cell type-specific Cre recombinase-expressing mouse lines, this model will allow researchers to apply in vivo experimental setups that have thus far not been possible. For instance, it may become possible to reveal the effect of, e.g., ABCC1 knockout in capillary endothelia of the blood-brain barrier on drug distribution to the brain, the treatment of brain tumors, or its effect on amyloid- β pathology in Alzheimer's disease mouse models.

In summary, our data revealed a performance of *hABCC1^{flx/flx}* mice with regard to protein expression and function. Thus, we conclude that we have successfully achieved our goal of developing an *Abcc1* humanized mouse model with knockout capabilities.
