ABSTRACT

We report here that overexpression of Rad23, a protein related to the ubiquitin-proteasome system, renders yeast cells resistant to methylmercury. Rad23 has three domains: it has two ubiquitin-associated (UBA) domains that bind to the multiubiquitin chain of ubiquitinated proteins; and it has a single ubiquitin-like (UbL) domain that binds to proteasomes. To examine the mechanism of acquisition of methylmercury resistance that is induced by overexpression of Rad23, we expressed variants of Rad23 in which one or other of the two types of domain was defective in yeast cells. In cells that overexpressed full-length intact Rad23, we detected elevated levels of intracellular ubiquitinated proteins, and the cells were resistant to methylmercury. By contrast, cells that overexpressed Rad23 with a defective UBA domain were not resistant to methylmercury and contained control levels of ubiquitinated proteins. Yeast cells that overexpressed Rad23 with a defective UbL domain exhibited enhanced resistance to methylmercury and contained even higher levels of ubiquitinated proteins than cells that overexpressed intact full-length Rad23. Rad23 is known to
have two mutually contradictory functions. It suppresses the degradation of ubiquitinated proteins by proteasomes via a mechanism mediated by the UBA domains, and it enhances the degradation of ubiquitinated proteins via a mechanism that is mediated by the UbL domain. Therefore, our findings suggest that Rad23 might induce resistance to methylmercury in yeast cells by suppressing the degradation of proteins that reduce the toxicity of methylmercury via a UBA domain-mediated mechanism.
Methylmercury is an important environmental pollutant, causing severe damage to the central nervous system as a result of passage across the blood-brain barrier (Castoldi et al., 2003; Clarkson, 2002; Sanfeliu et al., 2003). Many reports on methylmercury poisoning have been published but mechanisms of methylmercury toxicity, as well as bio-defense mechanisms against this toxicity remain to be clarified.

We have been studying the genes that are involved in resistance to methylmercury in yeast, a eukaryotic unicellular organism whose gene products have many functional similarities to those of mammals, including humans (Furuchi et al., 2002; Hwang et al., 2002; Miura et al., 1999; Naganuma et al., 2002; Naganuma et al., 2000). We demonstrated that overexpression of Cdc34, a ubiquitin-conjugating enzyme (E2) that is a component of the ubiquitin-proteasome system, induces a resistance to methylmercury toxicity in yeast cells (Furuchi et al., 2002).

The ubiquitin-proteasome system is involved in the intracellular degradation of proteins (Hershko and Ciechanover, 1998; Pickart, 2001; Pickart, 2004). In this system, multiple ubiquitin molecules are linked to substrate proteins by sequential
reactions that are catalyzed by ubiquitin-activating enzyme (E1),
ubiquitin-conjugating enzymes (E2) and ubiquitin ligases (E3). The multiubiquitin
chain that has been attached to a protein in this way allows the ubiquitinated protein
to be recognized by the 26S proteasome and degraded. When Cdc34 is
overexpressed in cells, ubiquitination reactions are activated and the degradation of
certain proteins by the ubiquitin-proteasome system is enhanced (Hwang et al.,
2002). The acquisition of resistance to methylmercury in Cdc34-overexpressing
yeast cells requires the ubiquitin-conjugating activity of Cdc34 and the proteolytic
activity of proteasomes (Hwang et al., 2002). Therefore, it seems likely that certain
as yet unidentified proteins that increase methylmercury toxicity might exist in cells,
and that toxicity might be reduced by the enhanced degradation of such proteins,
mediated by the ubiquitin-proteasome system, when Cdc34 is overexpressed
(Hwang et al., 2002).

In the present study, we examined the effects of Rad23, which is known to
interact with ubiquitinated proteins, on the acquisition of resistance to
methylmercury by yeast cells. It has been reported that Rad23 has two mutually
contradictory functions. One of the functions of Rad23 is the inhibition of
elongation of the ubiquitin chain via binding to the ubiquitin moiety of ubiquitinated proteins (Bertolaet et al., 2001; Chen et al., 2001; Ortolan et al., 2000; Raasi and Pickart, 2003). Because proteasomes recognize multiubiquitinated proteins as substrates when more than a certain number of ubiquitin molecules have been attached (Pickart, 2001; Pickart, 2004), it has been postulated that proteins can elude degradation by proteasomes when the elongation of ubiquitin chains is inhibited. The second function of Rad23 is the transportation of ubiquitinated proteins to proteasomes (Chen and Madura, 2002; Lambertson et al., 2003; Rao and Sastry, 2002). Rad23 binds to proteasomes, thereby enhancing the degradation of ubiquitinated proteins. Thus, Rad23 appears to regulate the degradation of ubiquitinated proteins via the mutually contradictory enhancement and suppression of such degradation. Here we found that, overexpression of Rad23 renders yeast cells resistant to methylmercury, and, in contrast to overexpression of Cdc34, the resistance might be induced by suppression of the degradation of proteins that is mediated by the ubiquitin-proteasome system.
Materials and Methods

Culture and transformation of yeast cells. The strain of Saccharomyces cerevisiae used in this study was W303B (MATα his3 can1-100 ade2 leu2 trp1 ura3) (Naganuma et al., 2000). Yeast cells were cultured at 30°C in synthetic dextrose (SD) medium. Plasmid DNA was introduced into W303B cells by the high-efficiency lithium acetate transformation method (Miura et al., 1999).

Construction of plasmids. The RAD23 and FLAG-RAD23 genes were amplified by the polymerase chain reaction (PCR) from yeast genomic DNA, as template, with the following oligonucleotides as primers: RAD23-F, 5’-CACAGAGCACACAAAGACAAC-3’; and RAD23-R, 5’-GTGAAGATACTTCAAGCCA-3’ for the RAD23 gene; and RAD23-FLAG- F, 5’-CATACAATAGAAAAATGGACTACAAGGATGACGATGACAAGGTTAGCT TAACCTTTAA-3’; and RAD23-R for the FLAG-RAD23 gene. The amplified fragments of DNA were ligated into the pKT10 yeast expression vector. Sequences of constructs were verified with an automated sequencer.

Quantitation of the toxicity of methylmercury in yeast cells. Yeast cells (10^5 cells/200 µl) were cultured in SD (-Ura) liquid medium that contained
methylmercuric chloride at various concentrations. To quantify cell growth, we measured the absorbance of the culture at 600 nm every 2 hr for 48 hr. For the colony-formation assay, we cultured yeast cells (10^6 cells/ml) in SD (-Ura) liquid medium that contained methylmercuric chloride (800 nM) for 3 h at 30°C. After treatment with methylmercuric chloride, yeast cells were seeded at a density of 10^3 cells per plate on agar-solidified SD (-Ura) medium, and formation of colonies was examined after culture for 2 days at 30°C. Yeast cells transformed with the pKT10 empty vector were used as controls.

**Site-directed mutagenesis.** Site-directed mutagenesis of the gene for Rad23 was performed, as described elsewhere (Furuchi et al., 2004); with a kit for site-directed mutagenesis from Stratagene (Cedar Creek, TX) according to the manufacturer's instructions. We constructed a variety of mutant RAD23 or FLAG-RAD23 genes by creating pairs of SacI sites in the open reading frame (ORF) of the RAD23 or FLAG-RAD23 genes and excising the fragments between the respective pairs of SacI sites. We amplified fragments by PCR using plasmid pKT10-RAD23 or pKT10-FLAG-RAD23 as the template and the following oligonucleotides as primers: 5’ UbL-F,
5’-CAACATACAATAGAAAAATGGAGCTCTTTAACCTTTAAAAATTTCAAG-3’; 5’UbL-R, 5’-
CTTGAAATTTTTAAAGGTTAAGAGCTCCATTTTTCTATTGTATGGTG-3’;
3’UbL-F, 5’-CATGTTTCTCAAAAAGAGCTCAGGAAGACCAAAGTAAC-3’;
and 3’UbL-R,
5’-GTTACTTTTGTTCTCGTGAGCTCTTTTTTGAGAAACCATG-3’ for deletion
of the UbL domain; 5’UBA1-F,
5’-CGGGATTCGTGGTGAGGAGCTCAGGAACGAGACCATCGAG-3’;
5’UBA1-R,
5’-CTCGATGGTCTCGTTCTGAGCTCTCTCCACCACGAATCCCG-3’;
3’UBA1-F, 5’-GAATATCTACTGATGGAGGAGCTCACCAGAAATCTGCGTC-3’;
and 3’UBA1-R, 5’-GACGCAGATTTCTGGGAGCTCAGTAAGATATTTC-3’
for deletion of the UBA1 domain; and 5’UBA2-F,
5’-CTTTCCAAGTTGACTATACCGAGCTCGAGATCAAGCTATTTCGC-3’;
5’UBA2-F,
5’-GCGAAATAGCTTGATCGTGAGCTCGGTATAGTCAACTTGGAAAG-3’;
3’UBA2-F,
5’-CAAATATTCTATTCAGCGAGCTCGCCGACTGAGATTGTAG-3’; and 3’UBA2-R, 5’-CTACAATCTCAGTCGGCGAGCTCGCTGAATAGAATTTG-3’ for deletion of the UBA2 domain. After creation of each pair of SacI sites, the plasmid was cleaved with SacI and self-ligated. All mutations were confirmed by DNA sequencing. The resultant plasmids were designated pKT10-FLAG-RAD23\textsubscript{UbL\textgreek{d}}, pKT10-FLAG-RAD23\textsubscript{UBA1\textgreek{d}}, pKT10-FLAG-RAD23\textsubscript{UBA2\textgreek{d}} and pKT10-FLAG-RAD23\textsubscript{UBA1\textgreek{d}+UBA2\textgreek{d}}.

**Immunoblotting.** Cell extracts were prepared and immunoblotting was performed as described elsewhere (Hwang et al., 2002). To quantitate total ubiquitinated proteins, we cultured yeast cells that overexpressed FLAG-Rad23 or FLAG-mutant Rad23 to the mid-logarithmic phase of growth in SD (-Ura) liquid medium and collected them by centrifugation. We suspended the cells in buffer C [20 mM Tris-HCl (pH 7.5), 5 mM MgCl\textsubscript{2}, 1 mM EDTA, 50 mM KCl, 5% glycerol, 3 mM DTT and the protease inhibitors phenylmethylsulfonyl fluoride and pepstatin A] and lysed them using glass beads. The cell extracts were fractionated by sodium dodecyl sulfate-polyacrylamide gel (12.5%) electrophoresis (SDS-PAGE), and then
bands of protein were transferred to an Immobilon-P membrane (Millipore, Bedford, MA) and subjected to immunostaining with FLAG specific monoclonal antibodies (anti-FLAG M2; Sigma, Saint Louis, MO) or multiubiquitin-specific monoclonal antibodies (clone FK2; MBL, Nagoya, Japan) which recognize multiubiquitin chains of the polyubiquitinated proteins, but not free ubiquitin or the protein moieties (Fujimuro et al., 1994).
Results

We investigated the effects of overexpression of Rad23, which is a protein that interacts with the ubiquitin-proteasome system, on the sensitivity of yeast cells to methylmercury. As shown in Fig. 1, yeast cells that overexpressed Rad23 were much more resistant to methylmercury than control yeast cells, which harbored the empty vector.

Suppression of the elongation of ubiquitin chain by Rad23 is mediated by two ubiquitin-associated (UBA) domains (UBA 1 and UBA2: Fig. 2a). Rad23 binds to the ubiquitin moiety of ubiquitinated proteins via these domains, inhibiting the further elongation of ubiquitin chains (Chen et al., 2001; Ortolan et al., 2000; Raasi and Pickart, 2003). By contrast, the region of the Rad23 molecule that is required for the transportation of ubiquitinated proteins to proteasomes is the ubiquitin-like (UbL) domain that is located at the amino-terminus (Elsasser et al., 2002; Saeki et al., 2002; Walters et al., 2003). The UbL domain is strongly homologous to ubiquitin, and it has been postulated that Rad23 acts as a role as a shuttle that transports multiubiquitinilated proteins to the proteasome by binding to the proteasome via this domain (Chen and Madura, 2002; Rao and Sastry, 2002).
To clarify the relationship between the toxicity of methylmercury and the two contradictory functions of Rad23, we investigated the sensitivity to methylmercury of yeast cells in which we overexpressed truncated variants of Rad23 that were defective in either the UbL domain or one or both of the UBA domains as FLAG-fusion proteins (Fig. 2a). We confirmed the expression of each truncated protein in the respective lines of yeast cells by the Western blotting with FLAG-specific monoclonal antibodies (Fig. 2b). We found that yeast cells that overexpressed the Rad23 with a defective UbL domain (UbLΔ) were more resistant to methylmercury than the cells that overexpressed intact full-length Rad23 (Fig. 2c). By contrast, yeast cells that overexpressed Rad23 with a defective UBA1 domain (UBA1Δ) were less resistant to methylmercury than cells that overexpressed intact full-length Rad23. Furthermore, yeast cells that overexpressed Rad23 with a defect only in UBA2 (UBA2Δ) or with a defect in both UBA1 and UBA2 (UBA1Δ + UBA2Δ) were resistant only to very low level of methylmercury (Fig. 2c). We obtained similar results with yeast cells that overexpressed the respective Rad23 mutants without the FLAG tag (data not shown). Our findings suggest that the UbL domain in Rad23 might be involved in the enhancement of methylmercury toxicity,
while both the UBA1 and UBA2 domains might be involved in the acquisition of resistance to methylmercury toxicity. Moreover, the UBA2 domain might be more intimately involved than the UBA1 domain. The observation that yeast cells that overexpressed intact full-length Rad23 were resistant to methylmercury (Fig. 1) indicates that the functions mediated by the UBA1 and UBA2 domains might dominate those mediated by the UbL domain with respect to the acquisition of resistance to methylmercury, at least when Rad23 is overexpressed.

Chen and Madura (Chen and Madura, 2002) reported that overexpression of Rad23 increased the total amount of cellular multiubiquitinated proteins. Therefore, we examined the total amounts of ubiquitinated proteins in yeast cells that overexpressed the various truncated mutant forms of Rad23 as FLAG-fusion proteins. We found a marked increase in the total amount of ubiquitinated proteins in the yeast cells that overexpressed the intact full-length Rad23, as reported previously, and a still more marked increase in the total amount of ubiquitinated proteins in the yeast cells that overexpressed Rad23 with defect in the UbL domain (Fig. 3). In addition, we detected a marked reduction in the total amount of ubiquitinated proteins in the yeast cells that overexpressed Rad23 with a defect in
either the UBA1 or the UBA2 domain. The extent of the reduction was higher when
the defect was in UBA2 than when it was in UBA1 (Fig. 3). These results show
clearly that the UbL domain of Rad23 plays a role in reducing the cellular level of
ubiquitinated proteins, while the UBA1 and UBA2 domains play a role in the
opposite phenomenon and increase levels of these proteins. Thus, our findings
support the reported contradictory mechanisms of action of Rad23 in the degradation
of ubiquitinated proteins. The degradation of ubiquitinated proteins by the
proteasome is enhanced by UbL-mediated transport of ubiquitinated proteins to the
proteasome (Elsasser et al., 2002; Saeki et al., 2002; Walters et al., 2003), while
suppression of the degradation of ubiquitinated proteins results from inhibition of the
elongation of the ubiquitin chains of ubiquitinated proteins, which is mediated by the
UBA1 and UBA2 domains of Rad23 (Chen et al., 2001; Ortolan et al., 2000; Raasi
and Pickart, 2003).
**Discussion**

With respect to the two functions of Rad23, it is likely that methylmercury toxicity is reduced by suppression of the degradation of ubiquitinated protein via the UBA domains, while toxicity is increased by enhancement of the degradation of ubiquitinated proteins via the UbL domain. In the yeast cells that overexpressed Rad23, the activity of Rad23 that suppresses the degradation of ubiquitinated proteins might dominate the activity that enhances the degradation of ubiquitinated proteins (Fig. 3), explaining, perhaps, the acquisition of the resistance to methylmercury by Rad23-overexpressing yeast cells. Therefore, we propose that certain protein(s) in yeast cells are involved in the reduction of methylmercury toxicity and are degraded by the ubiquitin-proteasome system, and that Rad23 might play a role in enhancing the protective actions of these proteins against methylmercury toxicity by suppressing their degradation.

Heretofore, studies of each of the two contradictory functions of Rad23 have been performed independently. There have been few investigations to determine whether the two functions involve the same ubiquitinated proteins as substrates. The results in Figs. 2 and 3 indicate that sensitivity to methylmercury (Fig. 2)
decreases with increases in the amounts of ubiquitinated cellular proteins (Fig. 3). Thus, it is possible that Rad23 might mediate both the enhancement and the inhibition of the degradation of a single set of proteins that is involved in protection against methylmercury toxicity. An elaborate mechanism must exist to regulate the two functions of Rad23 whereby cellular concentrations of ubiquitinated proteins are controlled, perhaps via the involvement of Rad23-related proteins, which respond flexibly to various physiological conditions.

We showed previously that overexpression of Cdc34, a ubiquitin-conjugating enzyme, induced resistance to methylmercury (Furuchi et al., 2002) and enhanced the ubiquitination of proteins in yeast cells (Hwang et al., 2002). Cdc34 might confer the resistance to methylmercury by accelerating the degradation of some protein(s) that enhances methylmercury toxicity (Hwang et al., 2002). However, present study revealed that the activation of ubiquitin-proteasome system is not necessarily effective in preventing methylmercury toxicity. Unlike Cdc34, Rad23 reduces methylmercury toxicity by suppressing the degradation of the proteins that might reduce methylmercury toxicity. Nevertheless, we cannot rule out the possibility that both Cdc34 and Rad23 recognize, as substrate, the same proteins that
are indirectly involved in methylmercury toxicity, since Cdc34 is involved in protein ubiquitination and Rad23 binds to the ubiquitin chain of ubiquitinated proteins. However, when we overexpressed Cdc34 in normal and Rad23-defective yeasts, resistance to methylmercury was enhanced to almost the same extent in both lines of yeast cells (data not shown). Thus, it is possible that the binding of Rad23 to ubiquitinated proteins might be regulated by a mechanism that involves the recognition of substrate proteins and that the functions of Rad23 might not affect the protein-degradation system in which Cdc34 is involved as a ubiquitin-conjugating enzyme. Multiple proteins, that reduce or enhance methylmercury toxicity and are ubiquitinated, might be present in cells. The ubiquitin-proteasome system and related proteins might determine the extent of methylmercury toxicity by regulating the cellular concentrations of these various proteins.
